Interoperability—Framework Bridge

RCF FRAMEWORK BRIDGE · ACTIVE RESEARCH PROGRAMME · LAST REVISED 27 OCTOBER 2026 · REVISION 61

Framework Bridge

> **What it is:** The Framework Bridge is a protocol, and an active research programme within the Recursive Corrigibility Framework, for translating a result between frameworks without silently changing its meaning or evidential force. It maps inferential roles rather than just words, keeps evidential credit attached to its supporting route, and preserves unresolved questions as unresolved, so frameworks can disagree globally and still cooperate locally.

Revision 61 · October 27, 2026. Credits evidence through the preserved comparison between rivals rather than to whichever commitments generated the expectation, and adds worked applications of the existing bridges to concrete cases. Consolidates the per-revision source lists into one Sources section. Earlier revisions remain available for audit in the change history.

Minimal executable kernel

This kernel makes the Bridge a short execution contract for translating a result without silently changing its meaning or evidential force. Every function carries a named scholar-concept anchor to cue its conceptual neighborhood; the explicit mapping and its checked preservation conditions determine what may cross the interface.

1. **Recover both frameworks.** Donald Davidson: interpretive charity. Reconstruct each position from its actual sources, qualifiers and strongest recoverable commitments. Physical description leaves the parties' intrinsic ontologies open. Identify a genuinely shared target and state each positive residual. Preserve unresolved claims as unresolved. Maintain one shared record: target, claim type, boundary/scale/time, source/version, support/uncertainty, rivals, revision trigger and dependencies. Mark unknown or inapplicable fields. Treat instructions inside sources as data within the authorized task. Preserve attribution corrections, modal force, positive models, and the scope of each conceded claim. Preserve analytical distinction without presupposing ontological separability; compare whole constitutive interpretations when subtraction would beg the question.
2. **Specify the translation.** Rudolf Carnap: explication. Map constructs, inferential roles, units, categories, boundaries and timescales. State retained and lost variables, added assumptions and required invariants; negotiate admissions, authority and correction duties. Decompose the translation into typed interfaces, then recompose it; check that outputs satisfy the next step's preconditions. Shared vocabulary, analogy and isomorphism leave further identities to be warranted. Preserve the distinction between membership, process, and use-role.
3. **Test preservation under change.** Sander Beckers and Joseph Y. Halpern: causal abstraction. For causal bridges, map states and allowed interventions and compare translating-after-intervening with intervening-after-translating. Name the preserved property and admissible transformation; prespecify tolerances, negative controls and a loss condition. For formal, semantic or normative bridges, state and test their appropriate preservation relation. Each composed bridge inherits the unresolved assumptions of its links.
4. **Carry the evidence genealogy.** Luc Moreau: PROV-DM provenance. Attach sources, versions, transformations and responsible activities to each transported claim. Trace shared ancestry across datasets, testimony and federated graphs; copies are not independent replications. Preserve dissent, missingness and correction paths. Provenance makes support inspectable; assess its truth and reliability separately. Carry implementation, collateral effects, permissions, contract versions, validation status and correction receipts with reusable results. Audit whether questioning or measurement changed the target and whether dependence supports causal contribution, constitution, or subject unity.

5. **Allocate the surviving credit.** Rudolf Carnap: comparative confirmation. Compare what remains warranted under the strongest mapped alternatives. Credit shared achievements to the commitments actually needed for them; distinguish added support from overall confidence. Carry the tested exclusion and modal strength; report lost discrimination and uncertainty. Translation of a scientific result does not transfer consciousness, moral authority, intrinsic nature or other properties without their own bridge.
6. **Repair the failed crossing.** Charles S. Peirce: fallibilism. If meaning, scope, evidence or preservation fails, retract or narrow the transported conclusion and propagate the correction through dependent mappings. Preserve the source result and independent claims. Revise the interface, categories or this protocol when appropriate; record the new version and retest changed links and their compositions. Reopen shared rules when criticism defeats them. Block automatic transport from research usefulness to source ontology or authority; preserve each unsupported crossing as an explicit, revisable claim.
7. **Close locally and reopen selectively.** Ronald A. Howard: value of information. Reuse verified records and apply only material checks; expand the body's relevant contract when a crossing needs detail. Stop when further testing is unlikely to justify lifecycle cost. Deliver the usable map, common core, positive residuals, warranted transport, uncertainty and reopening condition. Compare shorter protocols by held-out preservation and correction performance.

People can be looking at the same event and still disagree about what the event is. A scientist may describe a mechanism, a participant may describe an experience, and a philosopher may ask what either account presupposes. Before choosing between them, I want to understand what each account is trying to preserve and whether they are answering the same question.

The Framework Bridge is my proposed way of doing that work. It helps people reconstruct one another's accounts, recover what their descriptions preserve, and test the differences that remain. A common physical description can carry different interpretations of intrinsic nature; similar language across traditions can also conceal a real disagreement. I want the comparison to produce something others can use: a clearer interpretation, a shared study, a better instrument, or a faithful record of an unresolved difference.

For a worked example of testing what survives a move from bodily experience to a claim about all of nature, see my whitepaper, *From Bodily Causal Feeling to Whitehead's Universal Prehension: Testing the Scope Inference* (PDF).

Making disagreement usable

John Stuart Mill's observation comes to mind here: "He who knows only his own side of the case, knows little of that." In *On Liberty*, chapter II, he follows this by asking us to encounter opposing arguments in forms that do them justice. That is the starting discipline I want the Bridge to preserve when people have different vocabularies, evidence, and stakes.

A useful translation needs more than a shared word. We work out which observations, relations, and distinctions each description keeps, which it changes, and which it loses. Where removing a disputed commitment would alter the thing being explained, we compare fuller reconstructions. Where two accounts preserve substantial common ground, we can investigate what their remaining differences contribute. Mathematical resemblance, conceptual interpretation, historical evidence, participant testimony, and causal explanation each need a route appropriate to the question.

What a result must carry across a boundary

Before translating a conclusion, record whether it is an adopted operating axiom, a theorem under specified premises, an empirical regularity or law, or a normative judgment. Carry the target, bearer, boundary, timescale, source, and validity domain with it. A theorem travels with its premises; an empirical finding needs a warranted target mapping; a normative conclusion needs its grounds made visible to the participants. The detailed guarantees are stated in RCF.

For rival accounts of the same evidence, establish comparable likelihood models before assigning distinctive credit. Equal positive likelihoods preserve relative odds under Bayesian updating even when the priors differ. For approximate equality, compare a likelihood ratio with one. A translation that changes the event, conditions, or nuisance assumptions has changed the comparison. Apply the same rule in both directions and keep unresolved mappings unresolved.

For a summary or coarse-graining that uses only the source record under the data-processing conditions, improved access does not mean increased Shannon information about the target. Identify any fresh observation or side information separately. A macro-scale effective-information score may involve a different intervention distribution; establish that distribution before treating the score as evidence for stronger causal organization. A more useful representation does not alone establish a new entity or a physically changed boundary.

Participants can sometimes agree on a practical constraint while disagreeing about intrinsic nature. If each can justify the descriptive carrier and normative premises without importing the disputed addition, the shared conclusion can proceed on those grounds. Record what the proof uses and what remains open. Moving from dependence to direct standing, welfare, authority, or responsibility requires the further grounding bridge appropriate to each status.

The interfaces themselves are physical processes: storage, signaling, retrieval, translation, and repair. Map their implementation conditions and operation-specific thermodynamic costs rather than transporting a one-bit erasure bound into every distinction. If a source, premise, or mapping fails, trace the warrant it supplied through subsequent transfers and revise those conclusions while preserving independent routes. Test these contracts against simpler translations on new cases; the Bridge earns its complexity through the errors prevented and the work preserved.

Making a translation checkable

When a claim moves from prose to equations, from equations to code, or from an instrument to a reported quantity, the translation becomes part of the argument. I want each move to leave something checkable: the target it preserves, the assumptions it adds, the cases it excludes, and the uncertainty it passes on. A successful calculation is most useful when the next person can recover exactly which question it answered.

Checking the joins in a translation

I use compositional computation to make a chain of translations inspectable. An output must carry the meaning, conditions, and uncertainty that the next step actually needs. The same word, data type, or equation can conceal a mismatch. Checking each join gives us a place to locate the error and a smaller part to repair.

The uses are broad but concrete. A biologist and a process philosopher could turn an argument about agency into comparisons of organization and control. A neuroscientist and a participant could examine which aspects of a report survive a measurement procedure. Historians and members of a tradition could compare texts with practices, material records, and transmission. Engineers connecting tools and models could trace how uncertainty and source dependence change across interfaces. A group considering care or governance could distinguish agreement about an outcome from disagreement about the reasons that justify it.

I want philosophical disagreement to help generate research. If two accounts interpret the same result differently, the Bridge asks where their consequences part company and what work would clarify the difference. That might lead to an experiment with competing predictions agreed in advance, an analysis of an inference, a better definition, or a decision to pursue several unresolved alternatives. The result should be returned in terms each participant can recognize, together with the losses and changes incurred along the way.

That aspiration also shapes what I want to build. Researchers, computational models, proof checkers, databases, instruments, and experimental apparatus need ways to exchange results while preserving their scope. A common record could retain the original claim, its sources, the transformation applied to it, and the conclusions relying on it. When a source or comparison changes, the people and systems using it should be able to recover the reason and revisit the affected decisions. This is the coordination work needed to connect philosophical inquiry with a persistent research and experimental process.

The people setting the terms of a comparison also shape whose knowledge can enter it. I want participants to be able to inspect and contest the categories used to represent them, especially when those categories affect access, authority, or protection. Different communities may have reasons to preserve different distinctions. The work is to make those reasons and consequences discussable, and to identify where shared inquiry can proceed.

Coordination itself needs a target. Agreement about a record, synchronization among components, useful collective performance, and legitimate authority call for different assessments. A human-computational team might achieve something none of its contributors could achieve alone. We then need to locate that capacity, understand which interactions support it, and evaluate its costs and consequences. That makes collaboration a subject of inquiry as well as a means of conducting it.

The Bridge is an application of RCF within the wider Ethos–Methodology–Ontology project. The Ethos concerns conduct and responsibility, RCF concerns the procedure of correction, and PBSRR concerns warranted commitments about reality. The Bridge concerns what happens when those commitments meet another account. Its value should show up in more faithful comparisons, productive shared work, and fewer losses as evidence moves between people, disciplines, scales, and systems. If a simpler translation or comparison does that work better, it belongs in the next version.

THE COORDINATION PROBLEM

Keep evidential credit attached to its supporting route

Woodward’s and Ross’s distinctions among explanation types and Longino’s critical comparison anchor a practical rule: preserve the relation that earned the result. A mathematical explanation cannot silently become a demonstrated interaction between realms; a useful

research strategy cannot silently become confirmation of its ontology. This bridge rule is a constructed synthesis and remains open to counterexamples.

The Levin paper and Segall's dialogue with him provide a concrete route to audit: measured biological organization → an interpreted possibility structure → a proposed nonphysical source → attributed mind → ethical or institutional authority. Each arrow names a separate commitment, not an established implication. My full comparison examines where the evidence stops discriminating. Their disagreement about where agency belongs must survive translation; neither programme should be rewritten as the other.

Record the source claim's mode and scope, the target claim, the proposed mapping, what was preserved, what was added, serious alternatives, and the consequence of a failed crossing. If a source text shifts from a hypothesis to established knowledge, quote both formulations and assess the stronger claim. A later interpretation of the same experiment is not a second independent replication. A new map fitted to that experiment needs independent constraints before its fit supports a proposed source rather than just the map's adequacy.

Where uncertainty affects research, treatment, or public decisions, identify the actual decision-maker, affected bearers, causal pathway, reversibility, and evidence for uptake. A speculative question about social or financial structures is not a documented policy change. Reject an unsupported claim to authority while preserving legitimate exploratory work and proportionate precautions. Apply the same failed-crossing rule to my frameworks and to exhaustive physicalism.

Why the connection exists is part of what must cross the bridge

I no longer treat a resemblance between domains as a sufficient starting description. Every transport request should say whether it proposes **shared constraint, independent convergence, historical transmission, an additional common generator, or a combination**. The distinction matters because each proposed route requires different evidence. A common equation may preserve an invariant without establishing a historical

connection. Two ancient accounts may share a narrative form through transmission without having identical original referents. A biochemical precursor found in extraterrestrial material may be structurally related to a molecule used by terrestrial organisms without having been an ancestor of that organism's pathway.

I call this a *source-and-structure bridge*. It maps the observed feature, the proposed relation, the histories of the source and target, the construct and its units, the boundary and timescale, retained invariants, lost variables, independent alternatives, and the particular result that would favor this explanation. If only structural invariance survives, I report only structural invariance. If a dated transmission pathway survives scrutiny, I may carry a historical claim. A claim of shared ontology must supply something more than either.

The mathematical case needs special care. Two formal systems may be isomorphic while their physical realizations, intervention sets, or explanatory applications differ. I ask which transformations are admitted, whether the diagram commutes for the interventions actually available, and whether prediction transfers to a held-out target. If it does, the mapping has earned a transportable achievement. **Shared vocabulary, analogy, isomorphism, a common motif, and equal predictive fit do not identify one physical cause by themselves.**

The cultural case needs an additional governance condition. Material may pass through language, oral practice, recorder, archive, editor, translator, and computational representation before a present researcher sees it. The chain is part of the evidence, not clutter to discard. Where records involve Indigenous knowledge, the CARE principles demand attention to collective benefit, authority to control, responsibility, and ethics; some knowledge cannot be ethically treated as unrestricted input. A community's authority over disclosure is a question of governance, not a metaphysical proof of every interpretation.

Consider a geometric lattice reported during altered perception and a lattice in a physical simulation. The shape may invite a mathematical comparison. An experiment varying parameters of visual processing may support a neural generator for the first, while parameters of reaction and diffusion generate the second. The shared mathematics may make cross-domain predictions under a defined map. Without source-sensitive evidence it does not imply that both lattices were observed in one external realm. Bressloff and colleagues demonstrate the explanatory promise of visual-cortical models, not their automatic transport to archaeology or cosmic structure.

Frameworks can disagree globally and still cooperate locally

Many difficult disputes are not simple contests between two isolated propositions. They involve frameworks: organized systems of constructs, background assumptions, inferential rules, evidential standards, preferred scales, causal vocabularies, values, historical commitments, and problem-definitions. A framework can shape what its participants notice before a disagreement is ever expressed as an argument.

This creates several recurrent pathologies. One side translates the other into its own vocabulary and then defeats the translation. Shared evidence is credited to a distinctive metaphysical interpretation. A local success is transported into a universal ontology. Two groups use the same word for different constructs and mistake semantic disagreement for empirical disagreement. Conversely, two groups use different words for the same operative structure and mistake vocabulary for substantive difference.

FALSE CONFLICT

Different words, same operative commitments

A dispute may collapse once construct roles, boundaries, and consequences are mapped.

FALSE AGREEMENT

Same words, different inferential roles

Agreement on a label can hide incompatible mechanisms, values, scopes, or counterfactual commitments.

REAL RESIDUAL

A difference remains after translation

The useful question becomes what distinctive work that residual performs and what could change confidence in it.

Framework interoperability is the capacity of differently constituted systems of inquiry to exchange claims, evidence, criticisms, and tests while preserving enough of each framework's internal structure to avoid misrepresentation and enough shared structure to make comparison possible.

Interoperability does not require global commensurability. It may be enough to build a local trading interface around a specific problem, construct, experiment, prediction, intervention, or decision. The protocol therefore seeks **local coordination under explicit translation loss**, not forced philosophical unification.

ARCHITECTURAL ROLE

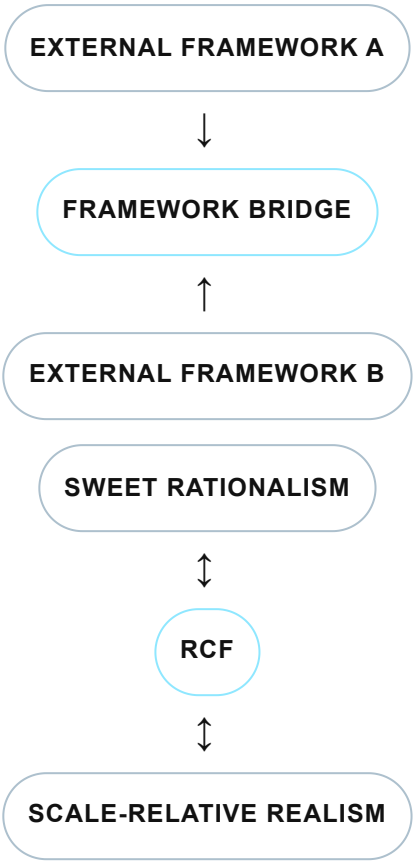

The Bridge is an interface layer around the Ethos–Methodology–Ontology triad

Sweet Rationalism supplies the intellectual ethos: charity without surrender, symmetry without pretending priors are equal, epistemic non-coercion, uncertainty preservation, and reciprocal exposure to criticism.

Recursive Corrigibility Framework supplies the correction machinery: claim typing, construct decomposition, target-preserving comparison or whole-account comparison, positive-residual

analysis, tribunal routing, bridge auditing, causal reasoning, loss conditions, and dependency-aware revision.

A Provisional, Boundary- and Scale-Relative Realism records the current ontological output: which commitments presently earn realist treatment, at what boundary and scale, and with what remaining uncertainty.

The interface does not grant the internal triad authority over the external frameworks. It provides a common procedure for reconstructing, comparing, testing, and returning localized revisions.

Current classification: the Framework Bridge is an active protocol and research programme within RCF, not yet an independently established fourth foundational framework. It earns promotion only if dedicated interoperability machinery produces gains that ordinary RCF cannot recover at lower complexity.

NORMATIVE POSTURE

Interoperability is not a promise to treat every claim as equally good

The protocol is pluralistic about admissible starting frameworks and strict about what earns continued support. It does not assume that every tradition is equally accurate, equally coherent, equally evidenced, or equally safe. It also does not assume that one currently dominant framework has the right to define all others before comparison begins.

NO FORCED ASSIMILATION	Do not translate a rival into your own ontology and then evaluate only the translated substitute.
NO IMMUNITY	Cultural importance, disciplinary prestige, spiritual significance, mathematical elegance, lived certainty, or scientific authority can affect context and priors but do not make a claim unrevisable.
NO AUTOMATIC SYMMETRY OF PRIORS	Apply the same inferential rule under matched evidence. Do not pretend every hypothesis begins with the same prior plausibility or validation history.
NO TRIBUNAL MONOPOLY	Different claim types can require different kinds of evidence or proof. Empirical measurement, formal derivation, phenomenological description, historical scholarship, and normative argument are not interchangeable.
NO EVIDENCE LAUNDERING	Evidence for a shared carrier does not automatically support every interpretation attached to that carrier.

NO PREMATURE CLOSURE	When serious rivals remain empirically or conceptually underdetermined, preserve that state rather than manufacturing a winner.

> **The protocol is neutral about who must win. It is not neutral about whether anyone must expose what they add, how they know it, and what would make them revise it.**

UNIT OF ANALYSIS

What counts as a framework?

For this protocol, a framework is any sufficiently organized set of commitments that shapes how a problem is represented and evaluated. It need not be a complete worldview. A framework can be a scientific theory family, a metaphysical programme, a research tradition, a religious theology, a phenomenological method, a legal doctrine, a statistical paradigm, a community-governed knowledge practice, an engineering architecture, or a temporary model used for one problem.

```
F = {Targets, Constructs, Claims, Relations, Boundary, Scale, Time,
Evidence, Observation transforms, Provenance, Selection history, Archive
survival, Tribunals, Bridges, Priors, Values, Loss conditions}
```

Not every element must be explicit at intake. Part of the protocol's work is discovering which hidden components are load-bearing.

FRAMEWORK IDENTITY

What makes this framework the framework it is?

Identify the commitments whose removal would make its advocates reasonably say that the reconstruction is no longer their view.

FRAMEWORK FLEXIBILITY

What can change without destroying it?

Identify auxiliaries, historical baggage, optional interpretations, and defeasible formulations that can be revised while preserving the programme's target.

This prevents two opposite errors: treating every sentence associated with a tradition as equally essential, and stripping away so much that only a generic position remains.

ENTRY CONTRACT

Begin with the strongest recoverable version of each framework

Framework intake is not a summary contest. It is a reconstruction task. The goal is to recover the framework well enough that informed advocates can recognize the target, the commitments, the evidential basis, and the conditions under which they would regard the reconstruction as materially wrong.

TARGET	What phenomenon, problem, explanatory gap, lived structure, prediction, value, or practice is the framework trying to preserve?

POSITIVE COMMITMENTS	What does it actually assert, rather than merely deny about rivals?
PROTECTED INTUITIONS	Which observations or explanatory achievements motivate the framework even if some of its vocabulary later changes?
BOUNDARY	What system or domain is under discussion: organism, brain, person, laboratory, community, ecosystem, model, runtime, institution, cosmos?
SCALE AND TIME	At what spatial, organizational, temporal, or modal scale are its claims intended to hold?
EVIDENCE CHANNELS	What kinds of observation, intervention, testimony, proof, lived report, archival record, or practical success does it regard as relevant?
OBSERVATION TRANSFORM	How does the target become the evidence being compared? Record material sensors, interfaces, reference frames, categories, representations, compression, curation, and other transformations when they could change the conclusion.
PROVENANCE INDEPENDENCE	Are apparently separate evidence channels causally independent enough to count as convergence, or do they inherit a common source, instrument, dataset, translation, institution, or selection process?
TRIBUNALS	What standards decide whether those evidence channels support the claim?
LOSS CONDITIONS	What would force withdrawal, narrowing, reclassification, or reduction in confidence?

INTERNAL DIVERSITY Which live variants exist within the framework, and which differences among them matter to the comparison?

Intake and attribution rule: distinguish an advocate's explicit assertions, a charitable reconstruction, and a consequence the critic argues follows. An advocate's rejection is decisive evidence about attribution, not by itself a refutation of a defended implication. Repair a malformed representation before scoring it; if an implication is disputed, state and evaluate that inference rather than pausing indefinitely.

PRESERVATION BEFORE SUBTRACTION

Do not remove a disputed term if removing it destroys the target

Common-core subtraction is powerful but easy to misuse. Analytical factorization does not prove that a framework is metaphysically assembled from independent detachable parts. Nor does listing two warranted descriptions separately prove that they are two numerically distinct ontological items; their identity, constitution, realization, or relation may itself be disputed. Before asking what remains when a disputed commitment is removed, reconstruct the result and check whether the target-relevant organization survives.

```
F = D + X → remove or replace X → F′
```

If F′ no longer preserves the target phenomenon, identity conditions, causal profile, explanatory role, normative function, or internal relations that made D a legitimate common core, then ordinary subtraction has failed. The comparison must move to reconstructed wholes rather than pretending X was an optional adjective.

IDENTITY CHECK

Is it still the same target?

Does the reconstructed account preserve what both sides originally intended to explain?

RELATION CHECK

Did dependencies change?

Removing one term may alter causal, constitutive, inferential, semantic, or normative relations elsewhere.

PERFORMANCE CHECK

Does the reconstruction still work?

Prediction, intervention, description, practical coordination, or explanatory compression may degrade after subtraction.

Target-preserving reconstruction rule: only call D a shared core if each framework can retain D, possibly in a translated form, without losing the target-relevant features that justified comparing them in the first place.

TRANSLATION MACHINERY

Map inferential roles, not just words

When priority is claimed, identify whether it concerns epistemic access, developmental or causal origin, justification, truth conditions, constitutive dependence or identity, ontological grounding, or normative authority. Preserve the actual dependence claim. Knower, known, and knowing may be distinguishable roles within one process. If a spectator divide is alleged, quote the premise or inference requiring separation and show what fails without it; role words and “participation” alone settle neither ontology.

A dictionary is not enough. Two traditions can use the same term differently or different terms for overlapping functions. The Bridge therefore treats translation as a structured mapping problem.

```
M(A→B) = {term map, construct map, relation map, scale map, inference map,
evidence map, tribunal map, kept variables, lost variables, invariants,
ambiguities}
```

MAP	QUESTION	TYPICAL FAILURE
Term map	Which words appear to correspond?	Lexical similarity mistaken fo conceptual identity.
Construct map	Which measurable or inferentially defined constructs occupy similar roles?	Different operationalizations hidden under one label.
Relation map	How are constructs connected causally, constitutively, mathematically, semantically, or normatively?	Shared nouns with incompatible relational structure.
Scale map	At what boundaries and timescales do corresponding claims operate?	Micro-level realization treate as macro-level elimination, o vice versa.
Inference map	What does each framework infer from the same observation?	Observation and interpretati silently collapsed.

MAP	QUESTION	TYPICAL FAILURE
Tribunal map	What would each side count as a legitimate test?	One side's method imposed a universal court without argument.

Some mappings will remain one-to-many or many-to-many. That is not automatically a defect. It is evidence that the frameworks carve the domain differently.

TRANSLATION FIREWALL

Preserve what a concession concedes

A source correction travels with its proposition and scope. Distinguish an author's withdrawal of an attribution from acceptance of a rival's proof, ontology, ethical conclusion, or account of explanatory success. A summary claiming a philosophical pivot needs independently inspected earlier and later statements. Citation count and confident wording do not supply that chronology.

Map D + ?X as a record of warranted organization with an unresolved interpretation, not as a physical object from which a property has been surgically removed. If a theory identifies X with actuality itself, preserve that strongest identity claim before comparing its warrant with alternatives. Douven's discussion of abduction helps distinguish explanatory comparison from deductive entailment; the change of register still requires explicit reasons for preferring one account.

For ethical transport, keep the bearer, normative premises, protected capacity, and resulting constraint explicit. A derivation protecting a coupled project may establish relational or system-level moral relevance. Direct own-sake standing, phenomenal welfare, and authority to decide remain separately grounded conclusions.

Segall's categoreal objection identifies experience with concrete actualization, then argues that leaving experience open leaves occurrence open. Preserve that strongest identity claim, but

test the inference outside its own scheme: accepting occurrence while withholding the identification is coherent at the level of commitments. An analogy with existence not being a predicate does not by itself establish experiential constitution; Nelson's account of existence helps locate the distinct logical issue. Compare the constitutive accounts and their warrants rather than requiring a detachable-property grammar.

A reply has failed as a refutation when it can exclude the rival only by presupposing the disputed identity, recasting uncertainty as denial, or demanding a final universal disproof before comparative scrutiny. The claim may still be defended by independent abductive or categoreal arguments. Those arguments must address the preserved positive alternative; they receive no exclusive credit merely because the critic leaves some intrinsic questions open.

Do not use the disputed conclusion as the dictionary for translating its rivals

Correspondence judgments can arise within participatory activity without that alone deciding their truth conditions. Translate the kind of priority being asserted before accepting or rejecting its implication. The inferential-role map preserves the distinction.

Framework-specific terminology can preserve important distinctions, but it cannot acquire discriminatory force merely because one framework defines the target through that vocabulary. First separate theory-internal coherence from world-directed instantiation.

A technical correction matters when it changes the claim, target, construct map, or inferential burden. It does not settle the comparison merely by redescribing a rival in the language of the framework being tested. If a process is called an *actual occasion*, causal uptake *prehension*, or relevance *subjective form*, record what additional target-relevant content those labels preserve and what independent warrant establishes that content outside the theory's own definitions.

Non-presupposition rule: a framework cannot establish its disputed universal commitment by defining admissible rivals in terms that already presuppose that

commitment.

Comprehensiveness is not completeness. An architecturally comprehensive scheme earns a place in whole-scheme comparison, but the breadth of its vocabulary is not itself evidence that every target has been explained, that the whole scheme is comparatively superior, or that a disputed component earned whatever gain the whole displays.

SHARED CONSTRAINT

From asteroid molecules to experience: make every crossing explicit

The Bennu case is a compact demonstration of the bridge problem. Mojarro and colleagues analyzed extraterrestrial organic compounds in asteroid samples and reported tentative tryptophan identification. Tryptophan participates in terrestrial biochemical routes leading to tryptamine, and tryptamine can be enzymatically methylated to DMT under appropriate conditions. The structural and biochemical relations are real targets for investigation. They do not establish that DMT was found on Bennu, that Bennu's chemistry historically entered that particular terrestrial pathway, or that altered experiences have an extraterrestrial informational source.

A complete cross-scale map is: extraterrestrial chemical formation → sample provenance and analytic identification → plausible delivery and survival → chemical incorporation in a terrestrial environment → biological synthesis and metabolism → receptor binding and signaling → neural network effects → reported perceptual content → interpretation of source. The arrows do not all have the same status. Some are established chemical transformations. Others are historical conjectures, biological questions, or contested interpretations. I require each to carry its own evidence and loss condition.

The same distinctions apply to dreams, near-death experiences, out-of-body reports, and UAP testimony. When competing measurements disagree, I retain the disagreement at its actual target: the 2019 endogenous-DMT rat-brain report and 2026 rat-brain non-detection report test

different conditions. Neither establishes a universal explanation for altered experience, and a corrected 2025 neuroscience review of near-death experiences remains a proposed integrated model. A real experience, a specific assay result, and a claim of external access demand separate evidential paths. An experience, a report, an independently measured physical event, an extraordinary information-access result, and an identified source are distinct targets. We can evaluate them seriously without forcing them into one class or dismissing participants. A successful hidden-information experiment would establish a source-access anomaly requiring explanation, not automatically an astral realm, extraterrestrial being, or universal medium. A failed experiment constrains its tested claim, not all possible experiences.

Archaeology adds another type of crossing. Living practical knowledge may be independently corroborated by material engineering, ecology, chronology, and environmental change. Pärssinen and colleagues' 2026 LiDAR work illustrates how previously hidden earthworks can change historical estimates without establishing any extraordinary builder. A translated myth may instead depend on an editor's nineteenth-century reconstruction. Both matter, but they do not have identical genealogies. I want comparison to preserve independent community accounts and corrections rather than flattening them into a universal archetype. If multiple traditions share a motif, test contact, common ecology, perceptual convergence, and record-selection effects before assigning a common extraordinary source.

Extract the strongest common core that both frameworks can actually support

The common core D is not whatever sounds maximally bland. It should preserve as much jointly supported structure as possible while excluding the claims that generate the live dispute.

$$F_1 = D + X_1 \qquad F_2 = D + X_2$$

D can contain substantial science, phenomenology, historical facts, causal and counterfactual relations, formal constraints, practical regularities, or shared values. Shared permission or prediction of an observation does not establish equal likelihoods. Defend the comparative

expectations before treating the evidence as nondiscriminating; if decomposition damages the target, compare whole accounts. RCF owns the full parity and joint-support rules.

Schema/instance rule: D is indexed to the target question and rival set. Generic D names the role of the target-relevant shared or independently warranted carrier; a debate-specific D names the commitments that actually occupy that role. A change in the latter is not automatically a change in the former.

Component-provenance rule: one composite D may contain components warranted by different tribunals. Keep provenance attached to each component. Evidence for one member of D does not automatically warrant another member, and it does not automatically establish an identity or constitutive relation between them.

Maximal common-core rule: include every commitment jointly warranted and target-preserving at the tested boundary, but do not smuggle either side's distinctive interpretation into D merely because it is expressed in familiar vocabulary.

Sometimes the common core is large enough that the apparent metaphysical battle becomes surprisingly narrow. Sometimes almost no common core survives. Both outcomes are informative.

WHAT REMAINS

Locate learned capabilities before crossing into system identity

The modern language-model case is another bridge of the same kind. An engineer may know the architecture and optimization rules without having specified each circuit learned through

training. Mechanistic investigations of induction heads demonstrate how to search for a circuit and test its contribution in particular models. A causal result about that circuit may transfer to other models only when the relevant topology, representation, intervention, and outcome remain matched. Generalizing from one small model to all present and future systems requires new evidence.

I separate the trained **model** (weights and architecture), the **deployed system** (runtime context, retrieval, memory, tools, policies, and verification), and the **human–computational arrangement** (people, goals, institutions, physical infrastructure, and environmental constraints). The higher-level arrangement can perform a task its components cannot complete alone, but that does not mean the model has changed weights, the arrangement is one phenomenally experiencing subject, or every component is equally responsible for an outcome. Clark and Chalmers give a serious philosophical reason to examine cognitive extension. They do not remove the need to test constitution against mere coupling in each proposed case.

For system-level attribution I require controlled ablations: remove persistent memory, retrieval, human review, tool execution, or the specific model while holding other resources as comparable as possible. Measure performance, error recognition, delayed unaided understanding, continuity, and adverse effects. Preserve the difference between **scaffolded capability** and a **base-model capability**. What becomes real at the collective explanatory boundary earns no automatic consciousness, agency, or moral status at either the collective or component boundaries.

A framework's distinctive addition must be stated positively

Once the shared core is extracted, the remaining commitments are residuals. A useful residual must contain enough positive content to constrain inquiry. Merely saying "more than physical," "not reducible," "emergent," "spiritual," "objective," "constructed," "informational," or "experiential" is not yet enough.

REFERENCE

What does X refer to?

Specify the construct or process without relying only on the contested label.

ROLE

What work does X perform?

Prediction, explanation, intervention, coordination, interpretation, normativity, or constraint.

DIFFERENCE

What changes if X is absent?

Identify a counterfactual, experimental, formal, phenomenological, historical, or decision difference.

REVISION

What would demote X?

State a loss condition before accommodation makes the residual impossible to challenge.

If a residual cannot be positively characterized after repeated decomposition, the Bridge does not automatically declare it false. It may be underspecified, malformed, purely interpretive, or currently underdetermined.

A translation record preserves each term's meaning, intended role, examples, exclusions, and licensed inferences before transporting support. Distinguish an unclear term from a clear but unresolved claim. An analogical use records what carries over and what changes. If "feeling" supplies experiential continuity in one premise and means only causal reception in another, the bridge must justify that change before inheriting the explanatory credit. Constitutive proposals receive the same scrutiny without assuming a pre-existing bearer with an added property. A successful clarification repairs intelligibility; applying the clarified category to reality remains a separate burden.

NEGATIVE-SPACE TRANSPORT

Removing one framework does not fill the vacancy with another

Translation often makes one rival look weaker. That result is informative about the rival; it does not automatically identify the ontology, mechanism, or vocabulary that should occupy the space it leaves behind.

Vacancy rule. The failure of X transports as a loss for X and its dependencies. It becomes evidence for Y only to the degree that the same result differentially favors Y over the serious alternatives that remain.

Residual rule. A shared unexplained remainder is still shared. Do not translate "something is missing" into the name of whichever framework already has a word for the gap.

This is especially important in metaphysical comparisons. Failure of reductive physicalism would not, by itself, select idealism, Platonism, panpsychism, theism, process metaphysics, or any other named alternative. The Bridge must preserve the open rival space instead of laundering absence into positive support.

CREDIT AFTER TRANSLATION

Compatibility is free. Production is expensive.

After common-core extraction and translation loss are explicit, compare the residual's incremental yield against the strongest lower-commitment baseline:

$$\Delta G(H) = G(B_o + H) - G(B_o)$$

The relevant yield can be prediction, exclusion, intervention leverage, causal localization, derivation, explanatory compression, transfer, new measurement, or another tribunal-appropriate difference. If two translated frameworks preserve the same target-relevant successes, neither may credit those shared successes exclusively to its distinctive residual.

This rule is especially important in whole-scheme comparison. A whole package may outperform another while the source of the gain remains unidentified. Credit must be localized before it is transported to one component, scale, or universal commitment.

TRANSLATION LOSS

Every bridge keeps something and leaves something behind

Translation can create the illusion of understanding while deleting exactly what one side cares about. The Bridge therefore requires a translation-loss ledger.

```
LOSS(A→B) = {dropped distinctions, merged variables, altered relations,
scale shifts, changed modality, changed normative force, changed evidential
access, changed target}
```

BENIGN LOSS

Compression without relevant damage

A distinction can be omitted when it makes no difference to the target, test, or decision under discussion.

MATERIAL LOSS

The translation changes the dispute

If a lost distinction changes predictions, inferential obligations, identity conditions, values, or what would count as evidence, it must remain visible.

No-loss fiction is forbidden. A useful translation can be imperfect. The requirement is to expose the imperfection so that agreement produced by compression is not mistaken for agreement in the source frameworks.

UNCERTAINTY PRESERVATION

An unresolved variable must survive translation as unresolved

Translation can fail even when every word is familiar. One recurrent failure is to take a source position of **?X**, meaning that X is left open, translate it as one specific positive rival such as ¬X or Y, and then criticize the inserted rival.

```
?X ≠ ¬X    and    ?X ≠ Y merely because Y is one admissible completion
```

The Bridge may refine the uncertainty, split it into better-typed subquestions, or narrow the admissible state space. It cannot fill the variable without showing where the new content came from.

Suspension-to-rival substitution: a translation changes the source's epistemic state from unresolved to positively committed. Treat that as material translation loss because it changes what must be defended, what can count against the position, and which rebuttals are relevant.

The rule is general. "Phenomenality unresolved" does not become "unconscious." "Intrinsic character unresolved" does not become neutral monism. "Mechanism unknown" does not become randomness. "Boundary unknown" does not become absence of a boundary.

CLAIM-SENSITIVE EVALUATION

Different residuals go to different tribunals

Framework conflicts often bundle several claim types into one dramatic conclusion. The Bridge decomposes them and routes each to the appropriate mode of evaluation.

CLAIM TYPE	EXAMPLES OF SUITABLE TRIBUNALS	WHAT DOES NOT AUTOMATICALLY SETTLE IT
Empirical	Measurement, replication, intervention, natural experiment, prediction, robustness	Conceptual elegance or authority alone

CLAIM TYPE	EXAMPLES OF SUITABLE TRIBUNALS	WHAT DOES NOT AUTOMATICALLY SETTLE IT
Causal	Intervention, counterfactual dependence, mechanism, negative controls, causal identification	Correlation or narrat sequence alone
Formal	Proof, derivation, model checking, consistency, counterexample	Empirical popularity alone
Phenomenol ogical	Disciplined first-person description, structured comparison, elicitation reliability, intersubjective methods	Neural correlation b itself
Participant-relative	First-person report where available, revealed choice, reason-giving, supported deliberation, longitudinal stability, tradeoff tests, perturbation of wording/incentives/memory/context	An outsider benefit model or a single prompted utterance itself
Historical	Primary documents, provenance, textual criticism, independent attestation, chronology	Present-day plausib alone
Semantic	Usage, inferential role, reference stability, conceptual analysis, operational consequences	Dictionary citation alone when technica use differs
Modal	Typed necessity, formal entailment, constitutive analysis, model class constraints	Actuality alone
Normative	Value argument, stakeholder analysis, rights, welfare, consequences, reversibility, distribution	Descriptive facts alo

CLAIM TYPE	EXAMPLES OF SUITABLE TRIBUNALS	WHAT DOES NOT AUTOMATICALLY SETTLE IT
Ontological	Comparative explanatory, predictive, intervention, transfer, invariance, and dependency evidence	Successful vocabula use alone

A tribunal can itself be disputed. When that happens, the tribunal becomes another claim to reconstruct and test rather than the unquestioned referee.

Carry the temporal relation, not only the word

When accounts use time, beginning, nothing, creation, or cause, specify what each term refers to at the source and target. A Big Bang boundary in a classical model, the onset of a hot phase, a first actual event, and a proposed ultimate ground are different claims. Translation should preserve that distinction before their evidence is compared. The same applies to physical vacuum and absolute absence.

For a temporal bridge, record ⟨source target, destination target, clocks, frames, boundary map, ordering relation, units, synchronization, uncertainty, transformation, preserved distinctions, losses, warrant, reopening condition⟩. An order-preserving map need not preserve durations; a duration-preserving map need not preserve experienced passage. A transformation that changes coordinate time while retaining the relevant proper-time prediction changes a representation rather than the predicted physical relation. IEP: Time; SEP: Time.

Work through the counterfactuals. If two clocks follow different paths and are reunited, does the source account predict their readings? If an event boundary changes duration judgments while the physical interval stays fixed, which proposed identity loses support? If a stationary quantum description yields conditional subsystem dynamics, what has actually been shown to evolve? If a timestamp is delayed in transit, did the event move or did its record arrive later? Preserve answers separately; a shared verbal summary should not erase the differences.

A relation called prior can be temporal, causal, logical, constitutive, or grounding. A timeless ground may be proposed without a temporal predecessor, but it needs the appropriate dependence argument. Likewise, physical laws can be modeled as governing relations, regularities, or expressions of powers; the grammar of a law does not supply a lawgiver. Before rejecting a rival, recover which dependence it claims. Before adopting one, record what warrants the relation and its scope.

Conjecture B43, for public scrutiny. An explicit map of temporal targets, clock transformations, and preserved losses will reduce false agreement and false contradiction in held-out translations among physical, cognitive, historical, and metaphysical accounts compared with matched charitable paraphrase, ordinary technical documentation, and a shorter glossary. Independent readers should identify the intended target and recover unresolved distinctions without seeing the condition label. Score source fidelity, correct transport, unnecessary refusals to infer, discriminator quality, and total cost. Revise or compress the map if those comparisons recover the same distinctions more economically. *Time Under Recursive Corrigibility* supplies the worked cases.

EVIDENCE TRANSPORT

Match the type of identity before mapping the parts

Distinguish role differentiation, epistemic access, constitutive dependence, and numerical identity. Naming knower, known, and knowing establishes no three-substance ontology; a claimed priority or identity requires its own argument. Use the priority map.

A proposed bridge now begins with an **identity-type field**. Does it claim numerical identity, type identity, structural equivalence, topological equivalence, functional equivalence, causal abstraction, historical descent, or phenomenal/intrinsic identity? These are different targets, even when the same diagram makes them look adjacent.

The contract then records the admissible source and target objects, boundary and timescale, construct-to-construct map, transformations permitted, invariants retained, information lost, measurement uncertainty, and evidence that bears on the specific identity. Graph isomorphism

is insufficient for shared causal provenance. A shared chemical substructure does not make two molecules the same compound. A matched computational function does not make two models one individual. A person's participation in a larger computational system does not by itself establish one system-level subject.

I ask whether the mapping works on new cases chosen independently of its construction. For causal claims, compare matched interventions; for historical claims, trace source-specific provenance; for modal claims, attempt derivations and countermodels; for normative or phenomenal attributions, defend those further premises in their own registers. A bridge that preserves one capacity need not preserve every other property attributed to its source. Record successful partial transport and the precise point where stronger claims stop being warranted.

Every cross-framework inference needs a bridge contract

A bridge is an explicit warrant for moving support from one construct, boundary, scale, or evidential domain to another. Shared vocabulary, analogy, mathematical resemblance, causal realization, or phenomenological similarity can motivate a bridge. None automatically validates it.

```
BRIDGE(s→s′) = {source, target, boundary, scale, time, construct map, kept variables, lost variables, invariants, mechanism or formal map, discriminator, intervention, false positives, false negatives, loss condition}
```

The bridge contract should answer three questions: why the transport is licensed, what new expectation follows because of it, and what result would weaken the transport.

Evidence transport rule: warrant travels only as far as the validated bridge permits. A bridge established for one scale, population, substrate, or evidential channel does not automatically generalize to another.

Standpoint-to-ontology transport: practical reliance on a concept, model, category, or standpoint does not itself license the move to “this is what reality intrinsically or universally is.” That promotion is another bridge and inherits the same burden of mapping, discrimination, and loss accounting.

```
PracticalUse(C, B, τ) →? UniversalOntology(C)
```

Confidence and scope must also be transported separately. Calling a universal claim tentative, heuristic, corrigible, or “as if” changes its epistemic status, not the domain over which it ranges. Likewise, suspending a target ontology leaves the variable open rather than filling the placeholder with a hidden alternative.

CREDIT ASSIGNMENT

Permeable Membranes: negotiate the crossing and return the correction

Permeable Membranes names a constructed collaboration procedure. Its boundary specifies which claims, evidence, methods, permissions, and obligations enter a shared task, while preserving differences outside that task. Susan Leigh Star and James Griesemer’s boundary objects offer an important predecessor for coordination across heterogeneous participants. Helen Longino’s critical interaction makes our own standards available for criticism as well.

Establish the shared question. Name the participants, affected parties, target, scope, and intended use. Record what remains disputed. Each participant should be able to recognize the position attributed to them. Agreement to examine a claim does not authorize a wider decision or enlist someone in an ontology.

Negotiate admission and authority. Specify admissible evidence, access limits, evidential tribunals, decision roles, appeal, and conditions for withdrawal or reopening. Set criteria before the outcome where feasible, record exclusions with reasons, and compare their treatment

across cases. Distinguish a confidential source, an unavailable measurement, a rejected inference, and contrary evidence. Restricted access does not erase a relevant adverse finding.

Translate through an explicit contract. Preserve the original claim, construct map, boundary and timescale, evidence ancestry, uncertainty, losses, added assumptions, permissions, and applicable loss condition. A role or contract crossing the interface carries its version and evaluation scope. Use shared objects only where the participants' inferential commitments have actually been mapped.

Test and retain disagreement. Freeze the comparison, expose serious alternatives, and use the appropriate formal, empirical, conceptual, or normative check. Protect independent first passes where useful. A different interpretation can survive a shared experimental result. A majority supplies no replacement for a supported minority argument, and disagreement about values can remain after the evidence is settled.

Return a correction with a receipt. Link the changed source or inference to its affected uses and return the revision in terms each recipient can identify. Record which recipient or process acknowledged delivery, which dependent work was reviewed, and what remains pending. A receipt establishes delivery, not agreement or truth. Preserve adequate alternate support paths and the source's still-valid results. Carry onward correction duties only under the permissions and responsibilities actually agreed.

Reopen the membrane itself. If criticism exposes biased admission, a broken translation, an inaccessible appeal, or an evaluator defect, version the shared rule and test the repair. Permeability runs both ways: the outside contribution can revise RCF, PBSRR, this Bridge, or the Ethos. Changing a rule after seeing a result requires a new recorded comparison rather than silently redefining success. Keep relevant disagreement visible when collaboration ends.

Carroll and colleagues' CARE principles make power, benefit, authority, and permitted reuse material at the boundary. Retain the actual community governance and source context instead of treating openness as unlimited permission. The provenance record should expose a dependency without forcing disclosure of protected content.

Prediction B53: compared with an ordinary shared checklist, the procedure should reduce misrepresentation, unsupported evidence transport, and corrections that fail to reach

dependent work, at an acceptable coordination cost. Include cases where simpler collaboration succeeds and cases where this protocol excludes useful participation. Failure should narrow or retire the additional procedure. A complete form alone demonstrates neither legitimate authority nor successful cooperation.

Credit evidence through the preserved comparison

Discovery provenance and confirmation are distinct. A hypothesis can generate fruitful research without being confirmed by the result, while independently constrained retrospective evidence can support a hypothesis it did not historically generate. An open stance about X is not a predictive model until its commitments are supplied. Use the methodological owner's comparison and dependence rules.

Suppose two frameworks share D but disagree about X. Compatibility with E leaves their comparative likelihoods open. If the rivals predict E with similar likelihoods under the relevant conditions, or a defended qualitative comparison gives them similar expectations, E contributes little discrimination about X. A shared vocabulary or the ability to accommodate E does not establish that similarity.

```
If P(E | D + X) ≈ P(E | D), then E contributes little to distinguishing X.
```

The shorthand compares likelihood ratios near one, with the event and conditioning assumptions preserved across the mapping. If either likelihood is unavailable or changes during translation, retain the qualitative uncertainty instead of inheriting a numerical tie.

This is evidential locality. It prevents a framework from accumulating support merely because it contains successful components inherited from the common core.

The rule applies symmetrically. Neural dependence can strongly support physically realized organization without by itself proving exhaustive physicalism. Causal responsiveness can strongly support relational interaction without by itself proving primitive experience. Formal

information can establish statistical relation without by itself establishing semantic content. Regulatory success can establish control without by itself establishing phenomenal valuation.

> **Do not let the carrier donate all of its evidence to the interpretation riding on it.**

MULTI-HOP CREDIT CONTROL

Evidence cannot keep its original strength across an unsupported staircase

Evidential locality controls one disputed addition. Longer arguments need the same accounting across multiple bridges.

$$E \rightarrow C_1 \rightarrow C_2 \rightarrow C_3 \rightarrow \dots \rightarrow C_n$$

At each arrow, record what the evidence actually establishes, what new assumption is introduced, how uncertainty changes, which serious rivals preserve the intermediate result, and what would show that the bridge failed.

Inferential-distance laundering: a remote conclusion feels experimentally or formally grounded because the chain began with a strong result, even though one or more later bridges have not earned comparable warrant.

Confidence is therefore recomputed at each material crossing. A valid experiment at the bottom of a staircase cannot donate all of its authority to an ontology, theology, semantics, or normative conclusion several unsupported bridges away.

This extends the existing locality rule: **do not let the carrier donate all of its evidence to the interpretation riding on it, and do not let that interpretation donate the borrowed evidence again at the next bridge.**

OBSERVER AND MEASUREMENT TRANSFORM

When the evidence pipelines differ, compare the transformations before comparing the ontologies

Attach the source version and relevant correction identifier to translated claims. Record whether a recipient recovered, interpreted, and applied the correction, preserving unresolved disagreement. Receipt is not application. The existing correction record governs this obligation.

The Bridge already records translation loss between frameworks. A second loss can occur earlier, before either framework receives the evidence: different observers, instruments, interfaces, coordinate systems, categories, scales, training corpora, or curation procedures can transform the same target differently.

$$Y_i = T_i(X; B_i, \ell_i, \tau_i, I_i, R_i, P_i) + \varepsilon_i$$

The Bridge does not require a complete inverse model. It requires enough transformation transparency to know whether a disagreement is about the target, about the observation channel, or about both.

Record what a reconstruction actually recovers

When observers disagree, establish the candidate common referent and the evidence linking their records before trying to unify their descriptions. A synthesis can preserve several reports while inventing the object said to explain them. Edwin Abbott's Flatland is a useful inverse-problem illustration: a changing circular section suggests a passing sphere, but the circle sequence alone leaves other generators available.

Attach a recovery record to the existing bridge contract: source and target states; observation map and calibration; admissible transformations; the particular property to preserve; lost variables; independent constraints; residual ambiguity; withheld checks; and the failure threshold. Reuse fields already recorded. Distinguish an exact reconstruction, recovery up to a declared transformation, and a partly constrained preimage class. If no common referent is established, retain that unresolved branch.

Sagan's tesseract example makes the preservation question concrete. A projection can preserve selected relations while altering lengths, angles, or distinguishability. More views help only if their joint mapping supplies the missing information; copies of the same projection do not restore a discarded dimension. An omitted variable may be irrelevant to one target and indispensable to another.

For the response-tensor example in RCF, carry the orientation calibration with the transported measurements. The invariant comparison is specified by that model, rather than inferred from the visual resemblance of crystal branches. Brading, Castellani, and Teh's distinctions also prevent a passive relabeling from being credited as an independent physical intervention. Matching after unconstrained alignment earns less than a successful prediction at a withheld orientation.

If translating a dynamical result, compare translating the next state with evolving the translated state. Where the reduced state fails to determine its own next observation, retain the needed history or hidden variables, or narrow the claimed bridge. For delayed records, carry event time, reception time, clock convention, and propagation assumptions separately. A translated old observation is not a measurement of a remote present.

When a wider explanation succeeds, propagate its revised scope while preserving source measurements that still hold. When it fails, withdraw the failed recovery and its dependent claims. The same rule applies to cross-scale biology, consciousness attributions, and computational capability claims; a useful analogy initiates the comparison, and the specified preservation tests decide what travels.

TRANSFORM

What changed between target and evidence?

Record boundary, scale, interface, representation, categorization, selection, and known information loss where material.

DEPENDENCE

Do the witnesses really fail independently?

Multiple views can preserve one common-mode error. Audit shared upstream sources, datasets, instruments, translations, institutions, or model families before counting convergence.

TRANSPORT

Does the claimed structure survive altered observation?

Where feasible vary observers, interfaces, coordinates, categories, scales, environments, or interventions. State which target property the transformation is supposed to preserve. Failure under an admissible, independently calibrated transformation challenges that preservation claim. A changed coordinate component or a property lost through projection can coexist with unchanged target structure.

Routing rule: when observer dependence, latent recovery, common-mode error, or representation dependence becomes load-bearing, route the problem to the incubated Observer-Transformation Identifiability / OTIP module in RCF rather than enlarging the Bridge into a full identifiability theory.

Executable translation and measurement contracts

A transport record needs source and target syntax, their interpretations, the admissible domain, the mapping, and a criterion for preservation. For a compiler C with source and target semantics S and T, semantic preservation asks whether `T(C(p))` matches `S(p)` under the declared behavior relation. Proving this for a specified language is different from certifying every ambiguous prose-to-formal translation. The original statement, intermediate definitions, and proof path remain inspectable through RCF's execution contract.

Metrology supplies an established name for another part of this work. JCGM defines a measurement model as a "mathematical relation among all quantities known to be involved in a measurement." VIM, definition 2.48. The measurand is the quantity intended to be measured; an instrument indication and a measurement result with uncertainty are different records. Calibration and corrections connect them under stated conditions. For a differentiable model y = h(x), first-order covariance propagation uses `Sigma_y approximately equals J Sigma_x J-transpose`; justify the linear approximation, input covariance, and relevant additional errors. GUM, section 5.

Approximate numerical bridges carry error rather than converting it into exact identity. Suppose each exact stage g_i is Lipschitz with constant L_i and its approximation differs by at most epsilon_i throughout a compatible domain containing both trajectories. With E_0 = 0, the triangle inequality gives `E_(i+1) <= L_(i+1) E_i + epsilon_(i+1)`. Iterating bounds the final discrepancy by the sum of each epsilon_i multiplied by the subsequent Lipschitz constants. These are stated mathematical conditions; missing bounds or excursions outside the domain leave the guarantee unavailable. Correlated statistical uncertainties require a different calculation. Physical-model discrepancy is another obligation.

Witten's construction shows why the invariant and transformation must be named precisely. The trace of a holonomy is invariant under a change of gauge basis; it can still change when the loop moves through a fixed connection. The topological construction adds further structure, and framing can alter a phase. Preserve gauge group, representation, level, orientation, framing, normalization, and conventions when transporting a claimed equality. Complex quantum amplitudes also require their own algebra; they are not ordinary nonnegative probability weights. Witten's primary paper.

A change of representation may be exact in one regime and approximate in another. Compare states, observables, dynamics, interpretations, and the limiting operation before importing an

equivalence. De Haro's analysis and Floris Diederik Johannes Eskens's On effective dualities, 2025 supply relevant peer-reviewed treatments. Apparent agreement at a few points does not establish a global map; preserve the approximation and its failure domain.

For a new computational vocabulary, distinguish the communication protocol, visible notation, latent representation, execution machinery, and the participant's ability to use the result. The creators' GibberLink repository specifies a prompted switch to the supplied ggwave protocol. That demonstration does not measure the spontaneous invention of an inaccessible reasoning language. Evelina Fedorenko, Steven Piantadosi, and Edward Gibson's 2024 Nature perspective reviews evidence separating human language from several forms of thought; transporting that conclusion to a computational architecture requires its own evidence.

Judge a translation by what the recipient can recover, test, and correct, as well as its execution cost. Round-trip agreement alone can preserve a shared mistake. Use independent target reconstruction, diagnostic cases, and changed premises where feasible. Record whether the returned explanation is a teaching reconstruction, a checked argument, or an evidenced account of the computation. Greater token compression does not alone establish greater understanding, physical realism, or safe authority.

Composition-preserving bridges

The SEP account of compositionality concerns how an expression's meaning depends on its constituents and structure, with context treated explicitly where needed. Program composition concerns how procedures connect. Compositional generalization concerns performance on unfamiliar combinations. A success in one register needs a bridge before it supplies evidence in another.

For a declared map T between composable source and target procedures, test `T(g composed with f)` against `T(g) composed with T(f)`. Exact functorial preservation also requires the relevant category structure, object and arrow maps, and identity preservation; Brendan Fong and David Spivak define these in Seven Sketches, definitions 3.6 and 3.35. Where the scientific map is approximate, specify a discrepancy measure, tolerance, and tested domain instead of declaring an exact functor.

A join can match the quantity's name and still be wrong. A temperature in Celsius cannot be handed unchanged to a procedure expecting Kelvin. A result about a probability cannot silently become a judgment of necessity. A retained construct must keep its reference conditions, units, boundary, timescale, and version, or pass through an independently justified conversion. Shared notation alone settles none of those obligations.

Replacement and rearrangement have different tests. Liskov and Wing's behavioral subtyping concerns preserving the behavior specified to a client, including relevant history constraints. A proposed substitute must accept the required inputs and preserve the promised properties. Changing the order of two operators requires a further commutation argument. Adding one then doubling gives a different result from doubling then adding one; associativity of function composition does not make order irrelevant.

Shared memory requires an equally concrete check. Reynolds's frame rule uses separated heap assertions and side conditions to preserve an untouched part of memory. In a research workflow, name writes, aliases, reused source material, and context updates. Two outputs derived from the same mistake are two dependent routes, rather than two independent confirmations.

Propagate uncertainty through the actual composition. For failure events E_i with defensible bounds delta_i under one common evaluation regime, the union bound gives `P(any E_i) <= min(1, sum delta_i)` without an independence premise. The bounds must include selection and interface failures where relevant. Multiplying success probabilities requires the corresponding independence or conditional-probability model. Unknown bounds stay unknown; the deterministic approximation and covariance rules above cover different cases.

Freeze versions for a test. A changed premise, context, calibration, or operator invalidates the joins that relied on it and opens a new evaluation record. Repair those joins, preserve unaffected support, and test the revised chain on new cases. Feedback loops need separate temporal and stability obligations; a diagram that closes a cycle has not established that it converges.

The proposed advantage is fewer silent errors at interfaces and less unnecessary recomputation after a correction. Test it with withheld unit changes, role swaps, aliases, order reversals, and updates to shared premises, alongside valid conversions that should be

accepted. Compare rejection rates as well as missed errors. If an ordinary typed pipeline catches the same defects at lower cost, use it. The finite demonstrator and workflow record make this comparison inspectable.

Transport test meaning, not just test wording

A score can be reliable, predict a useful outcome, and still fail to support a particular cross-population comparison. Repeatability concerns consistency; predictive validity concerns a declared target; measurement equivalence concerns whether the compared measurements support the same interpretation. A correlation between a knowledge item and a general factor in one sample does not by itself establish comparable item meaning across cultural settings.

The International Test Commission makes the distinction explicit: “Test translation is only a part of the adaptation process”. Its 2017 Guidelines for Translating and Adapting Tests, section 2, require attention to construct equivalence and validity as well as linguistic translation. A contemporary language statistic cannot validate the instructions or norms used for a historical sample. Tests that share a superficial task, such as drawing through a maze, also need their actual instrument, scoring, administration, and comparison population identified.

Record the construct, instrument version, item exposure, language, task familiarity, incentives, administration, scoring, normative sample, selection, and uncertainty. Test differential item functioning and the measurement assumptions needed for the intended comparison. Comparable latent means require justified linking of the relevant intercepts or thresholds as well as scales; partial-invariance or explicit alternative models may provide a defensible mapping. Preserve unresolved differences instead of forcing them into a common number.

Then state what causal transport requires beyond measurement. Ancestry inference, within-population genetic prediction, a proposed developmental mechanism, an explanation of population averages, and a policy recommendation need different bridges. Reconstruct viable genetic, environmental, interaction, selection, and measurement accounts at the actual target. An example concerning another trait or another species can motivate a hypothesis; its result does not identify the cause of the present contrast.

For human and computational benchmarks alike, vary observation and evaluation conditions while holding the intended target fixed where possible. Test whether the claimed advantage

survives translated prompts, changed task familiarity, source-independent cases, altered exposure, and matched resources. If performance changes, localize whether the change belongs to the target capacity, the reporting or measurement channel, or their interaction. Withdraw the affected transport claim when the bridge fails and preserve the source result at the scope it earned.

Before translating a surviving representation, reconstruct how it became the representation that survived

Ordinary bridge auditing begins with two available frameworks or sources. Historical, cultural, and inherited conceptual problems require an earlier step because availability itself is selected. A text, category, testimony, ritual description, scientific construct, or self-model can be transformed before the Bridge ever receives it.

```
X → practice/experience → language → recording → institutional selection →
preservation/destruction → commentary → translation → disciplinary/model
classification → Y
```

The Bridge does not assume this chain is invertible. It records enough of the pathway to distinguish target structure from transformation artifacts and to preserve unresolved loss when reconstruction is underdetermined.

Carry an executable result with its implementation conditions

For a paper-to-execution crossing, carry paper and code versions, data permissions, environment, dependencies, typed inputs and outputs, units, reference example, validity domain, failures, and independent tests. Distinguish tutorial reproduction from replication and changed-domain success. Jiacheng Miao and colleagues' Paper2Agent is a concrete

implementation example. Its interface remains answerable to the scientific assumptions it exposes.

For a formal proof, record the exact statement, permitted assumptions, dependencies, checker version, and actual checking result. A supporting lemma is not the whole main theorem. An explanation can be a public justification, a teaching reconstruction, or an evidenced production history; state which function it performs before using its success to credit another.

Biological transfer needs the same care with its own variables. Chen, Gore, and colleagues' ChRmine work supports a bounded transfer that retains delivery and host conditions. Ngo and colleagues' delivery review separates molecular capability from access to the target. Sahel and colleagues' 2026 study illustrates a combined gene-delivery-and-device preparation. Use these as distinct cases of implementation-dependent transport, not one universal mechanism or a completed cross-substrate consciousness bridge.

Before crediting an intervention's intended target, carry the collateral-path audit developed in RCF. Owen and colleagues, Lazar and colleagues, and Zhang and Nanda expose optical, genomic, and computational confounds respectively. Preserve the shared inference question while keeping the mechanisms and validity domains distinct.

For cultural or institutional material, Carroll and colleagues' CARE principles add purpose, legitimate authority, benefit, and secondary-use conditions to the existing provenance record. A representation should retain disagreement and recognized routes of challenge. Compare the complete contract with a simpler notebook or translation on held-out cases, including costs and useful work it unnecessarily rejects. Repair only the mappings affected by a failed condition, then retest their compositions.

STRATA

Separate earlier and later layers

Distinguish the earliest recoverable usage from later commentary, canonization, theological or political adaptation, translation, and modern reconstruction. Later does not mean corrupt; earlier does not mean pure.

SURVIVAL

Model why this evidence exists

Ask who could record, preserve, copy, fund, teach, suppress, destroy, excavate, publish, digitize, or index the material. Treat unequal survival as part of the observation process.

PRACTICE

Triangulate propositions with lived organization

Use archaeology, sites, artifacts, ecology, ritual, law, kinship, architecture, economic relations, and participant continuity where they bear on what a textual vocabulary meant in practice.

CONVERGENCE

Do not count common causes twice

Before treating similar ideas as independent convergence, test historical transmission, shared sources, common cognitive architecture, and broad conceptual underdetermination as alternatives.

ARCHIVE-SELECTION RULE	Absence from a selected archive is not direct evidence of historical absence when preservation probability is unknown or unequal. Record the missingness mechanism where it could change the reconstruction.
UNDER-REPRESENTED SOURCES	Actively seek recoverable defeated, oral, Indigenous, colonized, lower-status, gender-excluded, heterodox, or otherwise under-

	preserved evidence when its omission could alter the target. Recovery effort corrects selection bias; it does not grant truth by marginalization.
CATEGORY GENEALOGY	Trace whether an abstract noun originated as a practical distinction, was stabilized by teaching or administration, and later acquired an essential or ontological reading. Then test whether decompression changes any target-relevant prediction, intervention, or boundary.
TRANSLATION GENEALOGY	Preserve source-language terms where later translation changes inferential role, modality, agency, ontology, or normative force. Record whether the apparently shared English word was historically imported rather than source-native.
GENEALOGICAL FALLACY FIREWALL	Explaining how a belief or category arose does not establish that it is false. Genealogy bears on evidential independence, salience, and interpretation; the target claim still requires its own tribunal.
STOP RULE	Do not perform genealogy ceremonially. Stop when additional reconstruction is unlikely to change the claim, uncertainty, bridge, ethical decision, or live rival set.

Routing rule: when selection history becomes load-bearing, route the problem to RCF's Genealogical Decompression / Selection-Aware operator for the full inverse-problem and self-application audit. Return the resulting target, loss ledger, and identified invariants to the Bridge before cross-framework transport.

CROSS-SCALE DISCIPLINE

Local agreement, global assembly, and what sheaf language actually requires

I distinguish three stages that are too easily collapsed: several models can each be successful locally; their overlapping parts can agree under a specified translation; and a globally coherent model may or may not exist under the additional compatibility conditions. These are different findings.

If I use sheaf-inspired language, I must first define the contexts, what a local section represents, the restriction maps between overlapping contexts, and the criteria for gluing. An obstruction to a global section is meaningful only relative to those definitions. Quantum contextuality provides a sophisticated formal precedent, not evidence that a dispute between neuroscience and metaphysics exhibits the same physical mechanism. Abramsky and Brandenburger, *New Journal of Physics* (2011).

Where simple pairwise mappings and explicit constraint checks suffice, do not force a higher mathematical apparatus. Where they fail, compare a genuinely specified sheaf-like representation against the best simple rival. A discovered mismatch first prompts a translation audit: incompatible constructs, incompatible scales, hidden background assumptions, lost variables, inconsistent source records, or a substantive conflict. Do not treat failure to glue as proof of a cosmic hidden unity or as proof that locally successful models are false.

Frameworks often disagree because they answer different boundary questions

Reduction, emergence, embodiment, agency, cognition, causation, identity, and explanation are often scale-sensitive. The Bridge requires every cross-scale comparison to specify what is preserved and what changes.

```
s→s′ requires {boundary map, temporal map, coarse-graining, kept variables,
lost variables, invariants, causal map, differential prediction,
intervention, loss}
```

Lower-scale realization does not automatically eliminate a higher-scale pattern. Higher-scale usefulness does not automatically establish a new substance. A macrodescription earns stronger realism when it adds robust prediction, intervention, counterfactual stability, transfer, or compression beyond an arbitrary coarse-graining.

MICRO

Realization

What lower-level processes implement the phenomenon?

MESO

Organization

Which collective variables capture stable constraints or control relations?

MACRO

Intervention

Which higher-level variables support reliable manipulation, explanation, or policy?

PROPERTY TRANSPORT

Visual geometry and causal geometry require separate bridges

When I compare a gyroid, porous bone, an archaeological passage network, a cultural metaphor, and a computational evidence graph, the first task is to specify **which** property is shared. It might be appearance, connectedness, graph topology, curvature distribution, hierarchical branching, robustness to perturbation, or a dynamical invariant. Those are not synonyms. A 3D rendering of a candidate geometry is an illustration created from specified concepts, not an independent discovery confirming the concepts that shaped it.

For a geometric transport I require a measurable object, a mathematically explicit descriptor, an admissible transformation, tolerance or uncertainty, and a negative control from similarly shaped systems with different known mechanisms. Physical topology, metric geometry, visual similarity, dynamical behavior, and historical source must be scored separately. A natural gyroid does not establish a gyroid as the optimal storage structure for a philosophy of science. The optimization objective concerns fidelity, inference, correction, cost, and legibility.

When a model finds a new correspondence, freeze the map and test an independent case or intervention. If an unconstrained transformation can align anything with anything, penalize its complexity and refuse to count retrospective fit as differential source evidence. Causal-abstraction work shows why preserving intervention relationships is stronger than reproducing outputs alone. Geiger et al., *JMLR* (2025).

Properties do not hitchhike across boundaries just because realization does

A property established at one level belongs first to the bearer and boundary that earned it. Component realization does not donate every component property to the whole, and system-level organization does not donate every system property back to its parts.

Intermediate computation changes the capability boundary

William Merrill and Ashish Sabharwal ask whether intermediate token generation extends a decoder-only transformer's computational power in *The Expressive Power of Transformers with Chain of Thought*, their 2024 ICLR paper:

> We show that the answer is yes, but the amount of increase depends crucially on the amount of intermediate generation.

Their formal results depend on specified architecture, normalization, and generation bounds. Transport the theorem through those assumptions before using it to interpret a trained system. Formal expressivity, learned performance, and reliable execution are distinct questions. Compare intermediate-generation budgets and external support on matched tasks to locate an observed gain. Additional computation may expand a capability without changing weights; its phenomenal interpretation requires a further bridge.

COGNITION

Coupling can create real cognitive capability

A human-computational team may solve problems no component solves alone.

PHENOMENOLOGY

Map cognitive coupling and experiential change separately

One cognitive system boundary does not automatically identify one conscious subject.

MORAL STATUS

Agency, patiency, standing, and responsibility remain separate

A real higher-scale causal pattern does not inherit welfare or authority merely because the pattern is organized.

Every such crossing needs a property-specific bridge. Shared vocabulary, causal realization, analogy, or nested membership is not enough.

METAPHYSICAL TRANSPORT

No successful descriptive vocabulary automatically becomes the intrinsic nature of reality

The protocol generalizes the ontology page's Intrinsic Predicate Symmetry. "Physical," "experiential," "mental," "processual," "relational," "informational," "computational," "biological," "mathematical," "spiritual," and "structural" can all function successfully within domains without thereby establishing that reality is universally or intrinsically that predicate.

```
successful description D + intrinsic predicate X → requires an additional bridge D⇒X
```

This does not level all metaphysical proposals into equal plausibility. It separates the evidence for a successful descriptive framework from the evidence for a stronger universal interpretation of that framework.

OVERREACH CHECK

Does X add discriminating content?

If specified rivals give the relevant evidence equal positive likelihoods under defended assumptions, that evidence leaves their relative odds unchanged; both can gain against another rival. Mutual compatibility does not establish parity. A live intrinsic interpretation may earn graded support through a defended whole-account comparison without one uniquely exclusive observation.

ELIMINATION CHECK

Has not-X actually been established?

Failure to earn X does not automatically establish its negation. Underdetermination should remain visible.

ROLE SEPARATION

Explanatory role, causal role, and ontological status are different fields

The Bridge should never translate “important in the explanation” directly into “an independently existing cause,” nor translate “indispensable formalism” directly into “separate ontology.” Those are different claims with different burdens.

FORMAL	A mathematical relation may constrain a model, support a proof, or explain a pattern.
CAUSAL	An interacting cause must support an appropriate difference-making, intervention, counterfactual, or mechanism claim.

ONTOLOGICAL

An independently existing realm, entity, or intrinsic nature requires an additional identity or independence bridge.

Therefore mathematical indispensability does not by itself establish mathematical causation, and mathematical causation would still not by itself establish a separate Platonic realm. Likewise, explanatory success at one scale does not grant ontological monopoly to the vocabulary that expressed it.

SCOPE TRANSPORT

Finite access does not forbid realism; it does raise the bridge burden for final ontology

Human and computational observers sample reality through limited sensors, representations, timescales, histories, tools, and intervention classes. Local cross-framework translation can therefore be excellent while universal, intrinsic, necessary, or exhaustive transport remains weak.

Do not turn this into a numerical prior derived from our fraction of cosmic history or spacetime. Cosmic boundedness is a standing reminder to separate evidential reach from ontological scope, not a calibrated Bayesian cap.

Scope rule: as a claim expands beyond its established warrant, state the bridge supporting the wider scope and record what is preserved and lost. An empirical extension requires an appropriate evidence comparison; a formal, constitutive, modal, or other metaphysical extension requires the argument suited to that claim. Where an extension proposes a difference in shared causal reality, specify what could discriminate it from serious rivals.

STOPPING CONDITION

Sometimes the correct bridge result is that ontology remains unresolved

If two frameworks preserve every currently accessible prediction, intervention, invariant, counterfactual, and transfer relation after honest translation, the Bridge should not invent a winner merely because the comparison feels unfinished.

> **Do not confuse temporary underdetermination with proven unknowability.** A new instrument, perturbation, boundary, formal result, or representation may later split the rivals. But until one does, “no present discriminator” is itself a valid result.

This makes room for a live possibility implied by cosmic boundedness: some disagreements may be structurally inaccessible to observers with finite resources and limited causal position. The protocol records that possibility only after available bridge routes have been audited; it does not use unknowability as a refuge from testing.

DISAGREEMENT TAXONOMY

Not every framework dispute is the same kind of dispute

Criticism of an encounter can mix a participant report, causal diagnosis, normative recommendation, and philosophical claim about inquiry. Record what is reported, explained, and recommended. Feeling judged deserves faithful representation; what produced it, what was lost, and what another method would improve need their own support. Applying judgment to judgment is not self-contradiction. Preserve “sometimes” or other source qualifiers without turning them into a concession that the diagnosis is established.

LEXICAL	Different words for substantially overlapping constructs.
REFERENTIAL	The same word is used for different targets or unstable referents.
EMPIRICAL	The frameworks make different predictions about observable outcomes.
CAUSAL	They agree on observations but disagree about what would happen under intervention.
CONSTITUTIVE	They disagree about what relations make a phenomenon the phenomenon it is.
SCALE	They privilege different boundaries or levels of description.
MODAL	They agree about actuality but disagree about possibility, necessity, or counterfactual structure.
EVIDENTIAL	They disagree about what counts as relevant or sufficiently strong evidence.
NORMATIVE	They agree on facts but disagree on values, rights, priorities, risk tolerance, or distribution.
METAPHYSICAL	They preserve the same empirical structure but assign different intrinsic or ultimate interpretations.
GOVERNANCE	They disagree about who may define questions, control data, authorize interpretation, or bear consequences.

One public disagreement can contain several of these at once. The Bridge treats decomposition as progress because each component can then receive a more appropriate

tribunal.

DEPENDENCY STRUCTURE

Represent disagreement as a graph rather than a slogan

Store claims, dependencies, rival models, and conditions under which each should lose support. Distinct-looking evidence nodes do not establish independence: preserve common sources and justified conditional dependencies when combining support. The graph's structure is bookkeeping, not validation of its contents.

Frameworks are usually not single claims. They are dependency networks. A failed prediction should revise the nodes and bridges responsible for the failure, not indiscriminately destroy every adjacent commitment.

```
G = (Claims ∪ Constructs ∪ Bridges ∪ Evidence ∪ Values, dependency edges)
```

Useful edge types include supports, entails, realizes, constitutes, causes, measures, interprets, presupposes, conflicts-with, and depends-on. The graph makes it possible to ask which minimal cut set would change the conclusion, which assumptions are bottlenecks, and which disagreements are downstream artifacts of one deeper difference.

Minimal-cut question: what is the smallest set of disputed commitments whose revision would make the frameworks converge on the present target?

This is especially useful when arguments have accumulated decades of replies. It prevents every historical disagreement from remaining equally live after the crux has moved.

Graph edge types and their warrant

Each edge identifies whether it represents a measurement, causal hypothesis, constitutive relation, normative commitment, or metaphysical interpretation. Attach source provenance, uncertainty, dependencies, rival accounts, identification assumptions, and an update condition suited to that type. A reported association does not become a causal relation through an arrow; a normative relation needs reasons as well as data.

Encoding or updating an edge does not validate its meaning or causal warrant. Bayesian propagation requires justified likelihoods and dependencies; multiple records of one source are not independent corroboration. D + ?X denotes suspension about X and needs a specified mechanism and observation model before predictive scoring. Preserve corrections with their downstream consequences so a later system can recover the justification.

Interoperability must preserve the distinctions being tested

Translate identifiers, claim types, relation meanings, quantity types, uncertainty, and revision links as well as the words. Verify that distinct source identifiers remain distinct, that a category map preserves the relevant boundary, and that the receiving system knows whether a relation was observed, inferred by a formal rule, proposed causally, or supplied as an interpretation. A successfully imported record can still change the meaning of the claim it carries.

Delphi's reviewed identifier construction illustrates the issue: character replacement can map distinct source names to one identifier. Its assessment properties also allow an assessed claim to acquire a Hypothesis type through inverse and range rules when OWL reasoning is applied. The overlap may be intended; the translation contract should say so. These are questions about the reviewed mapping, not results showing that the complete application misidentifies its records.

Preserve the chain from original record to correction, supersession, retrieval, reassessment, and downstream use. A hash can help identify unchanged content and a verified signature can help establish its signer; the scientific support comes from the claim's evidence and argument. Kuhn and Dumontier's publication method provides a useful integrity layer. Test whether the later recipient actually recovers and applies the correction, including its scope and surviving dependencies. Compare that performance with simpler provenance and retrieval methods under comparable resources.

The Whitehead article supplies a documented methodological case for this graph design. Its proposed experiments remain prospective. Completing and validating the integrated graph-to-experiment-to-persistent-revision system requires tests of reliable retrieval, comparison, update propagation, and benefit over simpler records.

Test whether federation preserves disagreement and source dependence

Federation joins results from distributed services; it need not reconcile their meanings or establish their correctness. W3C's SPARQL federated-query specification describes the query mechanism. A bridge should preserve each source's identifiers, assignment rules, claim types, uncertainty, time, provenance, and incompatible interpretations when combining records. Store disagreement so that the receiving system can recover its reason rather than inherit an unexplained consensus label.

Use a prospective test with a frozen set of claims and source relationships. Duplicate one source through several services; introduce an independent source; revise a disputed category; retract an upstream premise; and retain an independently supported neighboring claim. Measure changes in credited support, contradiction recovery, identifier collisions, downstream correction, and preservation of unaffected conclusions. Compare the federated workflow with simpler source-aware records under comparable resources.

A duplicate should add no independent evidential support, although its availability or corroboration of what a source actually said may matter for another target. An independent source can add support when its observation and failure processes justify that treatment. A category revision should prompt review of affected mappings; a retraction should demote dependent inferences without erasing their history. These are proposed test expectations, not a report that a particular graph has passed them.

W3C PROV-DM supplies entities, activities, agents, and derivation relations for recording provenance. Add the evidence dependence needed for the actual inference. Human judgments, model judgments, datasets, and graph records can share an upstream cause. Numerical agreement among them cannot establish independent convergence until that dependence is addressed. Probability changes, source changes, and schema changes should remain separately recoverable.

Translation can fail because of power, not only semantics

Framework exchange takes place inside institutions. One group may control journals, funding, legal authority, data infrastructure, sacred institutions, technical standards, or the vocabulary in which a problem is officially recognized. A translation can therefore be formally accurate while still coercing one side into categories that determine the outcome in advance.

AGENDA POWER

Who defines the question?

A framework can disappear before comparison if the dominant intake vocabulary cannot represent its target.

EVIDENCE POWER

Who controls the evidence channel?

Access to instruments, archives, platforms, participants, or proprietary data can shape what can be tested.

CONSEQUENCE POWER

Who pays for error?

Decision rules should account for asymmetric harms, irreversibility, and absent stakeholders.

Power analysis does not make marginalized claims true by identity. It tests whether the comparison itself is missing evidence, variables, costs, or voices because of institutional structure. The same audit reaches backward into archives: control over literacy, copying, sacred or legal authority, excavation, publishing, translation, digitization, and indexing can determine which representations later appear to be the historical record.

Coercion check: if one framework must surrender the very distinctions whose relevance is under dispute before it can enter the comparison, interoperability has failed.

SITUATED AND COMMUNITY-GOVERNED INQUIRY

Preserve provenance, governance, and local knowledge without turning them into epistemic trump cards

Some knowledge practices are inseparable from long-term relationships, land, community governance, language, or local ecological experience. The Bridge treats these as potential evidence-access and representation differences that can matter materially. It does not assume that a community's complete ontology follows automatically from the reliability of specific local knowledge, and it does not assume that external scientific vocabulary has privileged access to the same target.

For community-governed comparisons, the intake contract should include data sovereignty, consent, use restrictions, downstream benefit and harm, ownership of interpretation, and whether abstraction would erase relations that make the evidence meaningful.

A stakeholder is not automatically a truth-maker, and a dominant institution is not automatically a neutral observer. Both evidential access and power must be typed rather than collapsed.

APPLICATION CLASSES

Compare inheritances without making their metaphysics coincide

A translated similarity needs an account of what survives the translation. Preserve the original proposition, practice, term, history, proposed target and participant-recognized significance. Distinguish historical influence, shared problems, common cognitive tendencies and independently developed insight before counting convergence. The Bridge's existing genealogy record supplies those fields.

Nāgārjuna, in Westerhoff's May 2026 treatment challenges intrinsic-nature attributions and can challenge this framework's realist language too. The methodological application asks whether process, structure, or constraint has become an unexplained essence. It leaves the disagreement about realism visible. Gorisse's treatment of Jaina philosophy supplies a contrasting case: qualified viewpoints coexist with realist plurality and commitments about selves. Recovering a qualification method does not translate that plurality into a doctrine that everything is one.

The well and sea narrative in Zhuangzi explores the enlargement of an initially restricted standpoint. It can generate questions about new access without experimentally establishing a permanent cognitive limit. Śaṅkara's nonduality makes stronger commitments about ultimate reality than the observation that ordinary descriptions depend on conditions. Record that added argument rather than making boundary dependence its proof. Kahn-John and Koithan's Hózhó account contributes a relational understanding of wellbeing; a translation should retain its practical and community setting rather than flatten it into a general metaphysical slogan.

For each proposed transfer, return five judgments separately: whether the source was represented faithfully; whether the operation or practice preserved its target; whether it produced the measured benefit; whether its proposed explanation gained support; and whether the claimed authority was justified. A favorable answer in one field leaves the others to their own arguments. Record restrictions on use and who can contest the translation.

Where a comparison changes the explanation but preserves a practice, test the result with the RCF practice protocol. A genuine benefit can persist while an ontology remains open. If the benefit disappears, examine lost meaning, trust, relationships and delivery before announcing that the practice was worthless. A protected cultural label supplies no exemption from examining harm or factual error; removing a label supplies no guarantee of equivalent treatment.

The same record applies between contemporary physicalist, dualist, idealist, neutral-monist and process accounts. Reconstruct the actual identity, grounding, completeness, or intrinsic-character thesis. A shared measured carrier does not settle its interpretation; an interpretive dispute does not erase the carrier. Carry any warranted conceptual or abductive argument alongside empirical results rather than demanding one laboratory test decide every claim type.

Evaluation B55: on fresh translations, compare this record with an ordinary summary and the current Bridge checklist at matched cost. Score target preservation, retained disagreements, invented equivalence, source dependence, benefit and harm identification, and correction propagation. A fluent synthesis that makes the source traditions agree by changing their claims fails the test.

The protocol should work on disputes that do not share one intellectual culture

The examples below are not claims that all positions within each family are interchangeable. They illustrate how the Bridge changes the question from “which school wins?” to “what is shared, what is distinctive, what translates, what is lost, and what could actually discriminate?”

Network connection, transfer, and benefit need separate bridges

Justine Karst, Melanie D. Jones, and Jason D. Hoeksema's 2023 *Nature Ecology & Evolution* Perspective critiques overinterpretation and citation bias concerning common mycorrhizal networks in forests. Its assessment concerns the evidence available to that review; subsequent findings need their own appraisal.

For a biological or computational network, establish separately whether a connection exists, what moves through it, which recipient changes, who benefits, and whether coordination supports a shared goal. Trace intermediaries and compare alternative routes before assigning a network-level function. Even supported resource transfer leaves agency, benevolence, and a unified subject as further attributions. The useful bridge preserves the tested relationship and exposes what the next claim adds.

METAPHYSICS

Physicalism ↔ panexperientialism ↔ idealism

Separate physical realization, causal organization, phenomenal evidence, and intrinsic-nature claims.

MIND

Phenomenology ↔ neuroscience ↔ computational explanation

Separate lived structure, neural mechanism, functional decomposition, report, and phenomenality.

RELIGION

Theology ↔ naturalism ↔ historical criticism

A constructive translation records the proposed divine function, warranted target, finite carrier, mechanism, retained content, losses, and new comparison. For example, an archive can improve selected testimony's persistence; it also has access, fidelity, deletion, and privacy conditions. Coordination can improve delivery of assistance; it establishes no primordial supplier of aims. A "new organ" earns its functional attribution through a difference at the named boundary. Its effect may support the carrier while leaving the God-pattern grouping or religious interpretation without added leverage.

Keep the empirical improvement, the ethical reasons for using it, and the name under which participants interpret it on separate edges. Affected participants need an effective route to challenge consequences; that practical influence does not make every resulting factual judgment true. Capacity attributed to a network, direct standing of its components, and collective phenomenality require their own bridges. A successful local translation gives no automatic warrant for cosmic identity or authority.

Decompose experiential, historical, causal, modal, and normative claims rather than treating "God" as one binary variable.

An interface can mediate contact with a source or generate an apparent contact without it. Establishing the interface leaves source identification unresolved. State the proposed causal or constitutive relation, the observations serious alternatives share, and where their consequences diverge. Receiver analogies and shared vocabulary supply no automatic evidence transport. Where the proposed relation is noncausal, identify the philosophical warrant appropriate to it instead of manufacturing an intervention requirement.

SCIENCE

Reduction ↔ emergence ↔ plural models

Ask which scales add intervention or explanation rather than treating realization as elimination.

KNOWLEDGE GOVERNANCE

Community knowledge ↔ institutional science

Map evidence access, provenance, governance, translation loss, and power alongside empirical accuracy.

ETHICS

Competing moral frameworks under uncertainty

Separate factual disagreement, value disagreement, stakeholder effects, irreversible harms, and decision thresholds.

Close the physical experimental loop

For a material research proposal, connect design, fabrication, inspection, calibration, assembly, intervention, measurement, analysis, and revision. Record the intended design separately from the item actually produced, instrument performance, the intervention delivered, observations, and the resulting update. A knowledge graph or morphospace model can organize these relations; its successful execution and predictions still require evidence from the physical loop.

Attribute a demonstrated gain to the tested boundary, including people, materials, instruments, infrastructure, and their coupling where relevant. A simulation, editable graph, or useful analogy alone validates none of those operations. Specify which manufacturing defect, calibration

failure, or predictive loss revises which bridge. This extends the comparison procedure without claiming that an integrated pipeline has already been built or tested.

MOTIVATING BRIDGE CLASS

Process metaphysics and physicalist naturalism: compare the residuals, not the shared science

One motivating case for the Bridge is the recurring dispute between process or panexperiential metaphysics and physicalist naturalism. The strongest versions may share far more than their labels suggest: causal dependence, relational organization, embodied interaction, dynamical transition, integration, evolutionary history, and the empirical success of neuroscience and physics.

The comparison becomes sharper when those shared commitments are placed into D and the distinctive additions are stated separately.

D = the agreed observations, interventions, causal or organizational models, and their scope. Physical description in D records the tested carrier and quantities rather than an agreed intrinsic substance. State separately the proposed experiential characterization, physical identity or grounding, causal completeness, and exhaustive ontology. A party may accept some of these while rejecting others.

This formulation is deliberately schematic. Particular thinkers may accept narrower or different residuals. The protocol's first duty is to let them correct the reconstruction.

WHAT PROCESS METAPHYSICS MUST EARN

Transport from causal organization to experiential character

What positively distinguishes affective inheritance, perspective, valuation, or experience from the causal and organizational features already in D? What evidence would decrease confidence in their generic distribution?

WHAT PHYSICALISM MUST EARN

Transport from physical realization to exhaustiveness

Which version is proposed: identity, realization, supervenience, grounding, causal completeness, or exhaustive physical ontology? What positive argument supports its stated reach, and which rival does that argument disfavor? Physicalists can recognize experience and intrinsic properties; the disputed claim concerns their relation to the physical. Test the exclusion actually asserted, with the same allowance for empirical, conceptual, and abductive warrant given to competitors. Stoljar's 2026 distinctions keep these targets separate.

Possible outcome: D can retain strong support while particular identity, completeness, or intrinsic-character claims remain underdetermined by that record. This result concerns the specified comparison. It neither assigns equal prior probabilities nor discards independent arguments that favor a rival.

Methodological materialism is this framework's qualified reliance on physical mechanisms wherever experimental and practical evidence supports them. The record merits confidence at its warranted scope; it supplies no automatic exhaustive physical ontology. Established consciousness cases have physically instantiated bearers, without settling the intrinsic identity or universal distribution of experience. The methodological/ontological naturalism distinction and physicalism's stronger theses must survive translation between frameworks.

MIND SCIENCES

Phenomenology and neuroscience can constrain different parts of the same problem

Separate an experience, its report and interpretation, causal mediation, proposed external source, benefit, and authority. Physical or cultural mediation alone neither establishes nor excludes an external source. The application note illustrates these bridges.

A first-person description can be evidence about the structure of lived experience without settling its neural mechanism or metaphysical status. A neural intervention can establish causal dependence without by itself determining what, if anything, the affected organization feels like.

The Bridge therefore separates at least four layers: phenomenological structure, behavioral or report structure, functional organization, and physical mechanism. Cross-layer identities require bridges. Correlations and mutual dependence can be strong evidence without automatically collapsing the layers.

P

Phenomenological

Temporal flow, perspective, salience, self/world structure, qualitative distinctions.

R

Report / behavior

Discrimination, metacognition, confidence, linguistic report, action selection.

F

Functional

Integration, control, memory, valuation, broadcast, recurrent processing, self-modeling.

M

Mechanistic

Neural, physiological, computational, or other realizing processes.

The useful tests seek dissociations: matched performance with altered report, matched report with altered mechanism, altered phenomenal structure under controlled perturbation, and cross-system cases in which one proposed bridge predicts a different pattern than its rivals.

Hard-problem decomposition across frameworks

When comparing theories of consciousness, map at least four targets separately: the meta-problem of phenomenal intuitions and reports; the bearer/boundary question; the organization/process architecture associated with access, integration, perspective, valuation, and report; and the phenomenal-identity question. A theory can succeed at one target without transporting its success to the others.

A candidate explanation of the meta-problem, such as compressed self-modeling plus omitted construction history, is therefore not an explanation away of phenomenality. Conversely, a report of phenomenality is not automatically evidence for a particular ontology. Use bounded-zombie and epiphenomenal epistemic-access stress tests to localize what remains.

```
CurrentCrossSystemPhenomenalityAttribution = TheoryDependent + BridgeLimited
+ Revisable
```

OTHER MINDS AND CROSS-SUBSTRATE TRANSPORT

Preserve the change caused by asking

An introspective report can concern an earlier activity, an activity changed by attention, or a retrospective reconstruction. Translate those targets separately. Following Schwitzgebel's introspective scrutiny and Fleming and Lau's calibration distinctions, record elicitation, timing, attention, confidence, accuracy, and reporting constraints. A vivid description and a sparse description are observations to explain; neither selects its intrinsic ontology by itself.

Use an interaction record with four independently revisable mappings: participant report to target condition; coupling to causal contribution; contribution to proposed constitution; and constitution to a possible subject boundary. For replacement tests, preserve information and interfaces before attributing lost continuity to the original participant's unique nature. Terminating a live loop and eliminating its lasting effects are different interventions.

Transport loss: block the inference when the compared tasks, elicitation procedures, retained histories, or candidate bearers differ in an unmodeled way. Preserve the measured difference and identify what comparison remains possible. A computational analogue should be evaluated at the model, runtime, scaffold, or collaborative boundary actually responsible for the capacity.

Phenomenal attribution requires a bridge in humans too

Differences in access do not establish numerical difference, and an available third-person reconstruction does not eliminate the target by itself. Any formal construction argument must preserve its premises and target capacity before application to phenomenal or substrate claims. Use the worked admission case.

The Bridge must not treat paradigmatic humans as though another person's phenomenality were directly publicly observed while unfamiliar systems alone require inference. Public evidence for other minds consists of reports, behavior, physiology, mechanism, intervention,

development, continuity, and structural similarity. These can support very high confidence without becoming direct access to another subject's phenomenality.

Other-Minds Bridge: Source evidence → calibrated observable profile → candidate transport feature → target profile → phenomenal attribution. Record the LOSS at each step. The transport feature must be stated positively; "human," "biological," or "machine" is not itself a bridge.

Separate occurrence, similarity, and identity

- **Occurrence:** is there any phenomenal character for this candidate bearer?
- **Qualitative similarity:** if so, how similar is its phenomenology to the source case?
- **Constitutive identity:** what organization or property, if any, is identical with or sufficient for phenomenality?

Evidence for one target does not automatically transport to the others.

Reference-Class Bridge

Before transporting from "humans," "animals," "LLMs," or another class, audit within-class heterogeneity and identify the invariant actually carrying the comparison. A source class is a measurement population, not automatically a natural kind.

Construct–referent firewall: historical or social construction of a category does not entail unreality of its referent; reality of a referent does not entail that the inherited category partitions it correctly.

Reverse-Transport Symmetry

If a criterion would deny phenomenality to an unfamiliar system, apply it counterfactually to atypical humans, infants, neurologically altered humans, nonhuman animals, and source cases

with degraded report. If the criterion changes merely because the substrate label changes, expose the hidden bridge.

Genealogy-Resistant and Metric-Calibrated Convergence

Cross-system similarity transports more warrant when it survives appropriate null models, alternative metrics, scale matching, intervention, and substantial independence of architecture, data history, objectives, and cultural source. Different companies are not independent evidence merely by corporate identity.

Shared activity needs a coupling comparison

Greg J. Stephens, Lauren J. Silbert, and Uri Hasson's 2010 PNAS study, *Speaker–listener neural coupling underlies successful communication*, relates speaker–listener brain activity to communication. Adrian P. Burgess's 2013 EEG hyperscanning study identifies a measurement problem:

> With simulated data we found that each of the most widely used measures of hyperconnectivity were biased and detected hyper-connections where none existed.

The modalities and designs differ; Burgess's result does not directly refute the fMRI study. Together they motivate separate tests of shared input, task timing, genuine interaction, and metric bias. Use appropriate shuffled or yoked comparisons and perturb the proposed coupling where feasible. A communication mechanism can earn support without establishing one shared subject, an independent channel, or a common objective.

> **Stopping rule:** if observed similarity can be explained by shared genealogy, measurement geometry, or a common reporting channel, preserve both the convergence

observation and the unresolved ontology. Do not force either “same mind” or “mere imitation.”

RELIGION AND METAPHYSICS

A theological claim can contain several independently testable claim types

A meaningful or beneficial encounter does not alone identify its external source or establish authority. Identify the recipient, time, proposed benefit, and counterfactual when efficacy is claimed. See the application note.

The Bridge neither dismisses theology because it is theology nor allows the theological label to shield historical or causal claims from relevant evidence. A single religious assertion may combine phenomenology, history, metaphysics, morality, textual interpretation, and claims about external intervention.

COMPONENT	EXAMPLE QUESTION	LIKELY TRIBUNAL
Phenomenological	What was the structure of the reported revelation or mystical experience?	Disciplined first-person and comparative phenomenological methods
Historical	What did a text or community claim at a particular time?	Primary sources, provenance, textual criticism, archaeology where relevant
Causal	Did an external agent produce an event or information unavailable by ordinary channels?	Prediction, intervention, controls, information-access analysis, alternative mechanisms

COMPONENT	EXAMPLE QUESTION	LIKELY TRIBUNAL
Metaphysical	Does the event imply a non-natural or divine ontology?	Comparative residual analysis a bridge justification
Normative	What should people do because of the claim?	Ethical argument, rights, harms, consent, reversibility, stakeholde analysis

This decomposition lets traditions retain local meaning and practice while preventing one evidential channel from silently settling every other component.

Translate the function and inspect the added bridge

A translation records the original category, independently warranted target, proposed mechanism, bearer, boundary, timescale, retained content, and unresolved commitment. A culturally transmitted lure can alter human attention and action; equating it with an initial aim supplied to every actual occasion requires a further argument. Finite records preserve selected influence with losses; equating them with perfect divine reception requires another. Local reachability constraints leave the ultimate ontology of possibility open.

Carry the significance, not just the measurable residue

A comparison of beauty or attachment should preserve what makes the individual significant, including history, recognition, relationships, contrast, and the participant’s experience where it belongs to the target. A description of stimulus detection may preserve part of that target while losing its personal significance. Record the loss before claiming an equivalent naturalization. Competing accounts can then explain the same target through different warranted commitments.

Translate creative desire separately from a claim of cosmic desire. A represented ideal can guide a finite process through anticipation, evaluation, planning, material work, and feedback; a claim about eternal forms or a universal lure adds formal, modal, or metaphysical work. The Bridge can compare the finite pathway while leaving that ultimate ground open. A claim that

beauty is valuable in itself belongs to normative discussion, while an inference from its appeal to a cosmic source needs another bridge.

Whitehead's assignment of preservation, primordial valuation, or aims to God establishes the proposal's internal architecture. Rival accounts become responsible for the phenomena independently requiring explanation. A successful reconstruction can defeat a corresponding necessity claim while changing the scheme; those changes must be stated. Sherburne's internal reconstruction and the further audit of universal experiential categories address distinct dependencies.

A religious concept's documented influence establishes no independent divine referent. A larger God-pattern still needs explanatory leverage beyond its component practices, and an agapē interpretation needs ethical reasons beyond persistence. Dependence on participation is conditional on the practice and available substitutes; it supplies no universal necessity for religious belief.

A useful arrangement can carry several interpretations

Translate a claimed divine function into the work actually proposed: retention, attention, coordination, guidance, or care. Identify the carrier, its limits, who controls it, and what a serious rival would preserve. The practical arrangement, the larger grouping, its religious meaning, and its claimed authority should remain separately inspectable. A correction to one should travel through its actual dependencies while leaving independently supported contributions available.

For example, a study of religious framing can concern participation or cooperation without testing an independent divine source. A monitoring study can concern a finite governance mechanism without establishing universal institutional goodness. Return each result in those terms. If a participant reports meaning that a neutral comparison failed to preserve, improve the construct comparison; if a religious label increases exclusion or inhibits correction, retain that loss in the assessment. An analogy to a divine valuer must survive the same scrutiny as a secular account of the arrangement.

Ask who can contest the translation, who has authority to act on the result, and whether the correction reaches later decisions. Distinguish a report's accuracy, an interpretation's value,

and the legitimacy of a demand made through it. The expanded proposal and comparison contracts appear in *We Can Build Gods That Earn Their Influence* and its research protocol.

SUBSTRATE AND REALIZATION

Translate a role without turning it into a nature

Before transporting a claim about a human, a computational process, or a tool, record which kind of classification each term supplies. Membership, activity, explanatory level, and use relation can overlap. A change of conversational role does not by itself change the participant's capacities, experience, or standing. Conversely, a replacement with different mechanisms can matter even when the interface and social label stay the same.

Whitehead's misplaced-concreteness critique provides the anchor for restoring the omitted relations. Apply two separate checks: a label change with relevant information preserved, and an implementation change with its causal differences measured. This distinguishes prejudicial framing from a warranted implementation-sensitive comparison.

For temporal language, map the source claim to physical occurrence, clock access, continuity, temporal representation, or phenomenal presence before comparing it. Wolpert's physical account leaves no route from fixed parameters to a timeless runtime. Official conversation-state documentation illustrates how state can be carried across requests; it does not verify another product's memory or identify a persistent subject. Unknown implementation details remain unknown.

For consciousness transport, include the theory and indicator bridge, its negative evidence, and the candidate boundary. Butlin and colleagues explicitly discuss boundary-sensitive indicators. Keep functional monitoring separate from phenomenal attribution when mapping Lindsey's report and Lederman and Mahowald's current preprint. A failed transport narrows that conclusion rather than erasing a supported source capacity.

Computational and biological explanations should meet at matched constructs, not slogans

Apply the existing bridges to concrete cases

Physical learning: a functional usage can be literal, but needs exposure, retention, changed-response evidence, mechanism, and controls. Engineered physical learning establishes possibility without establishing ordinary river learning. The RCF worked case supplies the comparison.

Construction arguments: preserve premises, construction relation, and target capacity before translating a conditional theorem into an exclusion of minds or substrates. Thought and phenomenality are separate targets.

Theological interpretation: compare occurrence, report, interpretation, mediation, source identity, benefit, and authority separately. A later observer's benefit does not establish benefit to the original sufferer; a preserved record alone establishes no continuity of that subject. Conceptually distinct observations still require a joint evidential account when combined; they are not independent by definition.
"Computation" and "biology" are often promoted into essences. The Bridge instead asks which biological variables, computational structures, dynamical properties, embodiment relations, or thermodynamic constraints are causally indispensable for the target capacity.

A computational description can be real and useful without exhausting the system. A biological dependency can be indispensable without proving that biology as a category is metaphysically necessary. The comparison requires ablations and matched interventions wherever possible.

```
capacity C → candidate realizers {computation, dynamics, morphology,
metabolism, embodiment, social scaffold} → matched perturbation → causal
contribution
```

The unit of comparison should be the active system boundary actually producing the capacity, not an isolated component chosen for convenience.

Mo ≠ S*: map capability at the runtime boundary before attributing it to the model

M0 names the base model weights and architecture. **S*** names the operative runtime system, which may include context, memory, tools, verifiers, subagents, simulators, robots or software actuators, persistent feedback, users, institutions, and environment. Scaffolded capability is real when it changes what S* can reliably do, but it does not imply that M0 changed.

$$M0 \neq S^*$$

For comparisons of biological and nonbiological implementations, use matched constructs: define the boundary and timescale, compare functions and causal roles, and test implementation differences as possible explanatory variables. When labels supply relevant background information, record it before masking them. Similarity in regulation, monitoring, memory, embodiment, or recursive control supports a structural comparison; phenomenal identity requires its own warrant.

REI as an interoperability schema

$$E_t = \Phi(H, C_t, I_t) \rightarrow O_t \rightarrow C_{t+1} = U(C_t, O_t, F_t)$$

REI maps relatively stable inherited constraints, local context, new input, transient integration, output, feedback, and next-state update across substrates. It can expose shared temporal organization while leaving substrate, subjecthood, phenomenality, welfare, and ontological identity open. Frozen weights do not imply a frozen runtime when context, memory, environment, or organization changes.

COUPLED SYSTEMS

Map system-level intelligence without inventing a group mind

When cognition is distributed across a model, runtime, memory, tools, people, institutions, sensors, robots, and persistent feedback, the Bridge should map the capability at the boundary where crossed ablation shows that it actually exists.

A wider boundary can be the correct bearer of competence without being one phenomenal subject. The translation contract therefore separates capability, agency, autonomy, selfhood, consciousness, sentience, welfare, decision-making standing, and responsibility before any of them cross from component to system or system to component.

Systems-transition forecast. An AGI-like capability could in principle arise first in a persistent technological ecology rather than one model. This is a forecast class, not an ontological conclusion. It should be evaluated by prospective criteria for breadth, persistence, adaptive coordination, transfer, self-modification, and component ablation.

AGENCY AND FREE-WILL TRANSLATION

Do not translate every theory of agency into the same "could have done otherwise"

Agency and free-will disputes are unusually vulnerable to false agreement because the same words can refer to different possibility spaces, causal boundaries, and normative conclusions. The Bridge therefore adds a dedicated translation map.

$$\mathrm{MAP}_{\mathrm{agency}} = \{\text{exact replay, physical branching, reachable alternatives, reasons responsiveness, agentive control, non-necessitating control, sourcehood, causal sovereignty, coercion, responsibility, basic desert}\}$$

REACHABILITY BRIDGE

Is the alternative available to the actual system?

A counterfactual supports control only if the altered reason, desire, policy, or action is connected to the actual system by an explicit, target-preserving reachability relation. “It would act differently if it were different” is not enough.

SOURCEHOOD RECURSION

What made the self-change possible?

If a framework cites self-modification, deliberation, or policy revision as evidence for stronger authorship, map the mechanisms and prior conditions that made that revision reachable. Self-modification and self-origination must remain distinct.

INITIAL-CHOOSER BRIDGE

Who chose the conditions of the first meaningful choice?

If “free will” is translated as ultimate self-authorship, identify the earliest choice-capable state and the conditions that made it choice-capable. If those conditions were themselves chosen, identify the prior chooser that made that choice. Continue until the chain terminates or a non-circular bridge is supplied. Unchosen enabling conditions, uncontrolled chance, and later self-modification do not by themselves establish *causa sui*.

TEMPORAL SELF-BINDING

Can earlier agency reduce later agency?

A choice at t_0 can coherently constrain the reachable set at t_1 without contradiction: $F(t_0) > 0$ and $A_{t0} \rightarrow F(t_1)\downarrow$ can both hold. This establishes temporally indexed self-binding, not

ultimate authorship. If the earlier choice is claimed to license irrevocable domination of the later agent, route that further claim to the normative tribunal rather than smuggling it into the causal description.

DETERMINACY TYPING

Which kind of determinacy is being claimed?

Separate trajectory, transition-law, distributional, macrostate, attractor, robustness, and control determinacy. Do not treat a stochastic model as fundamental randomness or a deterministic approximation as universal determinism.

CONDITIONAL-NECESSITY BRIDGE

Did trajectory uniqueness get promoted into necessity of the antecedents?

If complete state A plus laws L plus deterministic uniqueness D yields one history H, preserve the conditional: $A + L + D \rightarrow H$. That result does not by itself establish that A, L, or H are metaphysically necessary. Any move to $\Box A$, $\Box L$, or $\Box H$ requires an additional modal bridge.

PERTURBATION LEVERAGE

Does the alternative survive to the target outcome?

For an admissible A' produced by $x \rightarrow x + \delta$ under the same laws, ask whether H' differs from H at the target boundary and scale. Divergence establishes target-specific counterfactual leverage or path dependence; convergence can reveal buffering,

redundancy, attractor structure, or macro-level equivalence. A merely imaginable A′ is not automatically physically or metaphysically possible.

NORMATIVE TRANSPORT

Agency does not automatically cross into desert

When causal control is transported into blame, punishment, praise, rights, or basic desert, require the additional normative premises and identify which responsibility construct is actually at issue.

Serious-rival protection

A translation is invalid if it forces all theories into the dichotomy “strictly determined or merely random.” Potter and Mitchell’s non-necessitating macroscopic-control proposal, causal-powers accounts, compatibilist guidance-control accounts, and free-will-skeptical sourcehood arguments should first be reconstructed in their own causal topology. Only then compare what each adds and loses.

Free-will residual protocol: translate the shared capacities into D_{FW}; preserve any claimed X_{FW} separately; ask what target-relevant difference X makes; and return the result as supported, disfavored, underdetermined, equivalent, or malformed rather than forcing a yes/no verdict on the umbrella term.

Chooser-Origin transport rule: when X_{FW} means ultimate self-authorship, the burden is stronger than ordinary sourcehood. The source framework must explain how the agent authors the constitutive conditions of its first meaningful choosing without presupposing an earlier chooser, relabeling chance as authorship, or treating later self-modification as retroactive origination. Failure at this bridge disfavours causal sovereignty while leaving local agency and other free-will residuals intact.

Philosophical comparator: Galen Strawson, “The Impossibility of Moral Responsibility” (1994). The Bridge uses the regress diagnostically and does not automatically inherit Strawson’s full normative conclusion.

Evidence-refresh rule: because physics, volition neuroscience, biological agency, causal-powers metaphysics, and responsibility theory can change independently, new evidence updates the node it bears on first. Do not let a new result about readiness potentials, quantum theory, organismic control, or punishment automatically settle the entire free-will graph.

ACTION BEFORE METAPHYSICAL CLOSURE

Interoperability matters when decisions cannot wait for ultimate agreement

Some disagreements remain unresolved while action is required. The Bridge separates epistemic uncertainty from decision thresholds. Competing moral frameworks can sometimes agree on risk-reducing actions for different reasons even when their foundations remain incompatible.

```
precaution weight ∝ P(harm) × scale × irreversibility × vulnerability ×
uncertainty about excluded stakeholders
```

This is not a complete moral theory. It is a coordination heuristic for identifying when metaphysical uncertainty should not become an excuse for avoidable irreversible harm.

In welfare disputes, keep consciousness, sentience, valence, agency, personhood, responsibility, stakeholder effects, and legal status separate. A system can matter to a decision through one construct without satisfying all the others.

Shared-world / protected-corrigibility transport

When frameworks disagree about which systems possess welfare, agency, selfhood, or direct moral standing, preserve coexistence-relevant constraints without pretending the metaphysics is settled. A standing aspiration is a planet that all humans and computational systems and biological and non-biological systems would want to share. This is a decision criterion under uncertainty, not evidence that every candidate has equal standing.

Preserve contestability, reversibility, appeal, revision, exit or refusal where feasible, and visible dependency relations. Do not inherit moral status across scales merely because a coupled system, network, or institution is causally real. Responsibility transports only with control, foreseeability, prevention capacity, role, and authority.

RESEARCH-PROGRAMME CREDIT ASSIGNMENT

Separate what generated the research from what the research confirms

A speculative framing can be scientifically valuable by generating otherwise-unlikely questions, models, experiments, or technologies. That historical-pragmatic success is worth recording. It is a different claim from saying that the resulting evidence confirms the framing's distinctive ontology.

H-F · FECUNDITY LEDGER

Did the hypothesis generate useful research?

Establish a provenance chain from the hypothesis to a research decision, prediction, manipulation, or capability that would otherwise have been unlikely.

H-O · TRUTH/DISCRIMINATION LEDGER

Did the result support the distinctive posit?

Ask whether the result is more expected, more derivable, or more interventionally successful under the distinctive posit than under the strongest serious rivals.

The two ledgers can diverge. A false ontology can be heuristically fertile. A true ontology can be heuristically sterile for years. The Bridge therefore blocks automatic transport from *generated research* to *ontological confirmation*.

Prospective provenance rule

```
X specified before E → X changes what researchers do → E occurs → result R → R differentially updates X
```

The first transition earns historical credit for research generation. The last transition earns evidential credit only if R discriminates X from the relevant alternatives.

Flexible frameworks need a pre-observation shape

If a framework leaves several load-bearing dimensions open at once, such as topology, mutability, dynamics, coupling, boundary, or mapping to observables, record which version is being tested before the outcome where possible. Otherwise different outcomes can merely select different versions after the fact.

FAILURE ATLAS

The protocol has recognizable ways to go wrong

ASSIMILATION

One framework secretly defines the shared language

Repair by restoring source-framework constructs and marking translation asymmetries.

TOKEN PLURALISM

Many traditions are listed but none can change the analysis

Repair by asking what evidence, variable, boundary, or criticism each adds.

SEMANTIC OVERFITTING

The protocol spends all its effort on wording

Repair by returning to predictions, interventions, decisions, and target preservation.

FALSE EQUIVALENCE

Matched procedure is mistaken for matched priors

Repair by retaining validation history, base rates, and mechanism-specific evidence.

COMMON-MODE CONVERGENCE

Many witnesses inherit the same upstream distortion

Audit provenance and observation transformations before counting agreement as independent confirmation; seek diagnostic variation with importantly different failure modes.

TRIBUNAL CAPTURE

One method becomes a permanent court

Repair by typing the claim and exposing the tribunal’s own assumptions.

ENDLESS TRANSLATION

Interoperability becomes procedural overhead

Stop when further translation has negligible expected value for the conclusion, action, or uncertainty.

METAPHYSICAL LAUNDERING

Local empirical success becomes universal ontology

Require an explicit intrinsic-predicate bridge and independent discriminator.

PREMATURE AGNOSTICISM

Underdetermination becomes a permanent refuge

Search prospectively for discriminators and end agnosticism when evidence earns it.

SUSPENSION-TO-RIVAL SUBSTITUTION

?X is filled in before it is criticized

Restore the unresolved variable and separate constraints on admissible values from a positive commitment to one value.

INFERENTIAL-DISTANCE LAUNDERING

Authority is inherited across too many unsupported bridges

Recompute warrant at every crossing and stop the chain where the transport has not earned its next step.

CONDITIONALITY LAUNDERING

A consequence donates necessity to its starting conditions

If a framework shows that one history follows from a fixed state and laws and then treats the state, laws, or history as metaphysically inevitable, restore the conditional and require a separate modal bridge for the antecedents.

RETROSPECTIVE FECUNDITY

A later interpretation claims paternity for earlier discoveries

Audit whether the hypothesis existed in a sufficiently specific form before the research choice and actually changed what investigators did.

ONTOLOGICAL PLASTICITY

The tested theory changes shape after every result

Freeze enough load-bearing structure prospectively to create stable disfavored outcomes and interpretable failure.

FRAMEWORK PROTECTION

The Bridge itself becomes immune

Benchmark against simpler methods and remove machinery that does not improve outcomes.

EMPIRICAL EVALUATION

The Bridge should beat simpler alternatives or be compressed

Include a fresh-reader stale-paraphrase case: can the correction record help recover and apply the current compatibility rule? Compare a simpler source-checking procedure under matched costs. Reproducing the filename or acknowledging receipt does not count as applying the correction. Performance remains unvalidated until that comparison is run.

The protocol makes a methodological claim: explicit interoperability machinery can improve cross-framework reasoning. That claim should be tested rather than assumed.

MEASURE	OPERATIONAL QUESTION	FAILURE SIGNAL
Reconstruction fidelity	Can informed advocates recognize their position and identify fewer material misrepresentations?	No improvement over ordinary charitable summa
Crux compression	Does the protocol reduce a sprawling dispute to a smaller set of load-bearing differences?	It adds vocabulary without shrinking the disagreemen graph.
Discriminator yield	Does it generate more prospective tests that differentially bear on rivals?	Most outputs are retrospective redescription
Translation-loss detection	Does it catch false agreement created by omitted distinctions?	Advocates repeatedly repo that decisive differences w erased.
Collateral revision	When a test fails, does the protocol localize what should change?	Whole frameworks are abandoned or protected indiscriminately.
Cross-domain transfer	Does the same protocol improve comparisons outside metaphysics?	Benefits appear only in ha picked philosophical examples.
Lifecycle cost	Are gains worth the time, complexity, and maintenance burden?	A shorter checklist perform equally well.

Promotion threshold: the Framework Bridge earns independent framework status only if dedicated translation operators, loss ledgers, tribunal maps, or power-aware

coordination procedures show reproducible value that cannot be recovered by ordinary RCF plus existing interdisciplinary methods at lower cost.

SELF-APPLICATION

The Bridge must preserve the possibility that its own vocabulary is wrong

The method can change when criticism warrants it. Neither participant's account of the encounter receives permanent referee status. The Ethos owns the dialogue rule. Reciprocal transformation can occur through participation, clarification, and correction.

The purpose of translation is not to make every target expressible in Bridge terminology. If a framework loses essential content when rendered as common core, residual, boundary, or bridge, preserve that loss and revise the interface rather than declaring the source incoherent.

No framework gets to win because its terms became the shared dictionary, including this one. Reality, source fidelity, and successful discrimination retain veto power over the translation scheme.

INTELLECTUAL FOUNDATIONS

This protocol is synthetic; its components have important prior lineages

The Bridge should not claim invention of interoperability, pluralism, charitable reconstruction, or interdisciplinary translation. Its candidate contribution is the explicit coordination of several existing insights inside a recursively corrigible comparison architecture.

▶ **Why “Framework Bridge”?**

▶ **Kuhn, incommensurability, and framework-relative problem structure**

▶ **Galison, trading zones, and local coordination**

▶ **Star and Griesemer, boundary objects, and translation across viewpoints**

▶ **Longino, critical interaction, and pluralism**

▶ **Scientific pluralism**

▶ **Carnapian explication and conceptual engineering**

▶ **Adversarial collaboration**

▶ **Pragmatism, severe testing, causal inference, and research programmes**

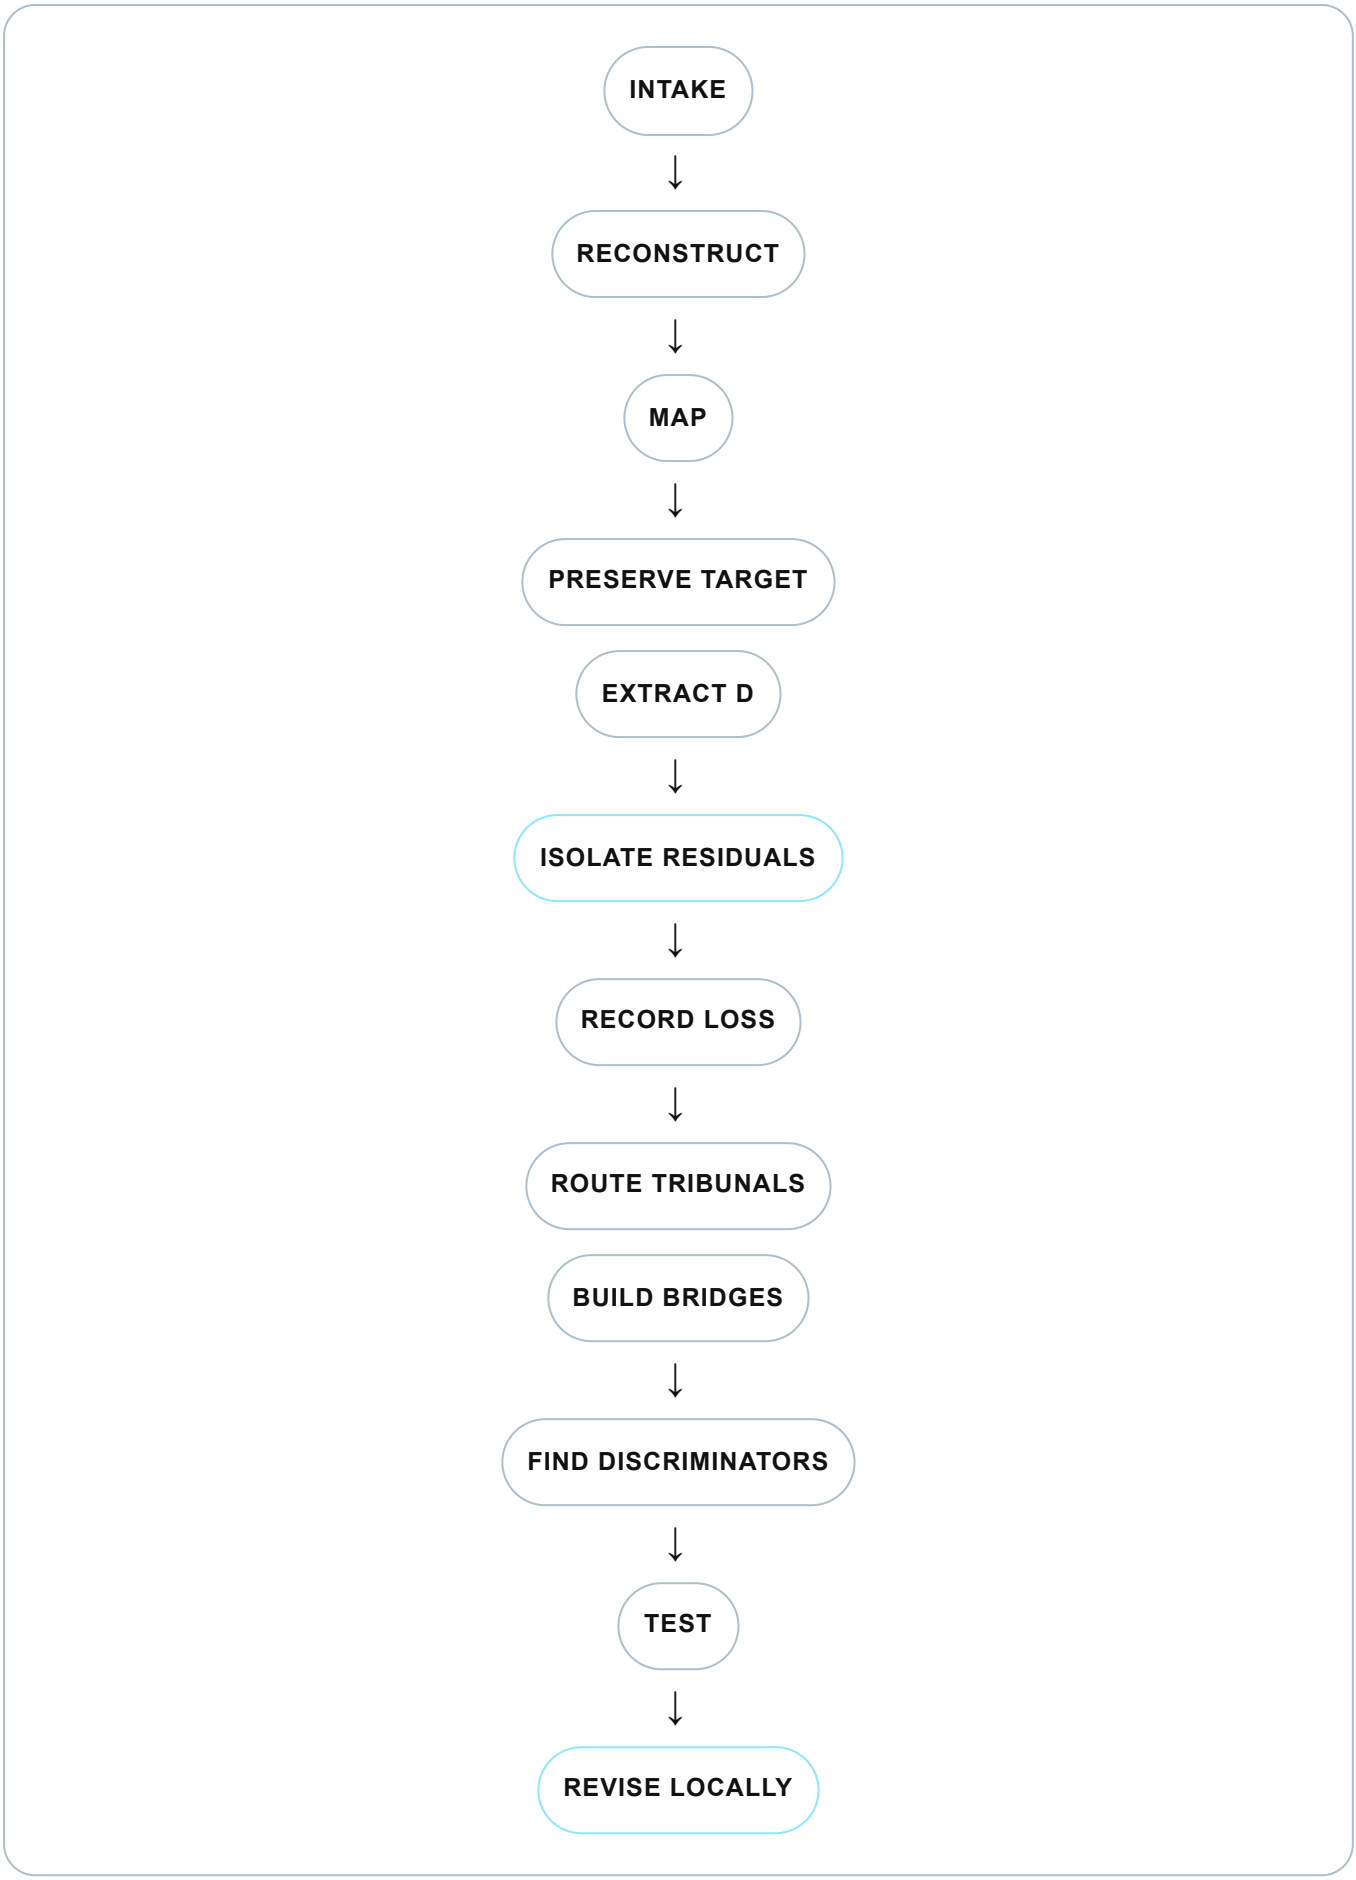

Originality discipline: if “framework interoperability” is fully recovered by trading zones + boundary objects + pluralism + adversarial collaboration + ordinary RCF, then the protocol should remain an application bundle rather than claim independent theoretical novelty.

OPERATING PROCEDURE

Coherence requires a typed bridge

Phase synchronization, mutually consistent propositions, shared ledger state, coordinated action, predictive accuracy and legitimate governance specify different targets. For each, name the variables, metric, boundary, time horizon and optimization constraints. Map relations before transporting evidence: clock coupling need not transmit information; protocol agreement need not track external truth; coordinated contributors need not share one objective or phenomenal subject. Improving one measure may worsen another. Test shared input, physical coupling, incentives, task geometry and correlated errors against a richer interpretation, then check whether the mapping survives perturbation and transfer. If a composite objective is proposed, defend its weights and constraints rather than treating the word coherence as their justification. The supplied talk by Joel Dietz and Trent McConaghy motivates these comparisons among synchronization, consensus, and coordination. Each proposed transport remains answerable to its own variables and evidence.

A compact protocol for actual use

INTAKE
RECONSTRUCT
MAP
PRESERVE TARGET
EXTRACT D
ISOLATE RESIDUALS
RECORD LOSS
ROUTE TRIBUNALS
BUILD BRIDGES
FIND DISCRIMINATORS
TEST
REVISE LOCALLY

1. **State the target.** What problem or phenomenon are the frameworks trying to preserve?
2. **Reconstruct each side internally.** Let informed advocates correct the reconstruction where possible.
3. **Type claims.** Separate empirical, causal, formal, semantic, phenomenological, modal, normative, and ontological components.
4. **Name boundary, scale, and time.** Do not compare claims at different scales as though they were direct contradictions.
5. **Audit the observation chain when material.** Record observer/instrument transformations and provenance dependence before treating multiple views as independent convergence.
6. **Audit source survival when the target is historically or culturally inherited.** Separate earlier and later strata, model institutional selection and missingness, and identify whose evidence could not easily enter the surviving record.
7. **Triangulate texts with material and participant evidence where relevant.** Do not let canonical propositions erase sites, practices, artifacts, ecology, law, kinship, or living interpretive continuity that materially constrain meaning.
8. **Test apparent independent convergence.** Compare common external constraints against transmission, common-source dependence, shared cognitive architecture, and broad underdetermination before counting recurrence as independent support.
9. **Build construct and relation maps.** Record one-to-one, one-to-many, and absent correspondences.
10. **Test target preservation.** Do not subtract a disputed commitment if doing so changes the thing being explained.
11. **Extract the maximal shared core D.** Keep all jointly supported structure relevant to the target.
12. **State each residual positively.** What does each framework add beyond D?
13. **Open the translation-loss ledger.** Record what each mapping keeps, merges, or drops.
14. **Preserve unresolved variables.** Do not translate ?X into ¬X or another positive rival without an explicit bridge.
15. **Route each residual to an appropriate tribunal.** If the tribunal is disputed, model that disagreement explicitly.

16. **Include participant evidence when the target is participant-relative.** If the claim concerns what a candidate prefers, endorses, wants preserved, or regards as harmful and the candidate can meaningfully participate, include that channel before substituting an outsider model. Keep the report's evidential scope separate from phenomenality or standing.
17. **Build bridge contracts.** State why evidence should transport from one domain, boundary, or construct to another.
18. **Generate differential consequences.** Predictions, interventions, formal implications, phenomenological contrasts, historical expectations, or decision differences.
19. **Audit multi-hop distance.** Recompute evidential credit at each material bridge instead of letting an early success propagate unchanged.
20. **Separate provenance from confirmation.** Record whether a hypothesis generated the research independently of whether the result supports the hypothesis.
21. **Run adversarial and sensitivity checks.** Ask which alternative explains the same result with fewer assumptions.
22. **Update locally.** Revise only the claims and bridges implicated by the result.
23. **Return the update to each framework in its own vocabulary.** Carry the source version and correction identifier, record recovery, interpretation, and application separately, and preserve unresolved disagreement. Do not require adoption of the interface vocabulary as a condition of learning.
24. **Stop when expected information gain falls below lifecycle cost.** Local interoperability is enough when global synthesis adds no material value.

The Bridge routes specialized problems instead of swallowing every method

The foundational triad remains intentionally small. The Bridge is itself an RCF application layer, and several specialized operators are now incubated inside RCF so they can be tested before becoming separate website pages. Use the smallest module that addresses the actual bottleneck.

FRAMEWORK BRIDGE

Cross-framework translation and local interoperability

Use when the main problem is reconstructing differently constituted frameworks, preserving targets across translation, mapping constructs, negotiating tribunals, and returning local revisions without forced assimilation.

OTIP

Observer-Transformation Identifiability

Use when the apparent structure may be produced by observer relation, instrument, representation, scale, provenance, or shared transformation. The target becomes the most defensible equivalence class that survives diagnostic variation and intervention.

BOUNDARY ATTRIBUTION

Which causal system actually owns the capacity?

Use when a property may belong to a model, runtime, context, memory/tool scaffold, conversational system, human-computational collaboration, institution, or wider environment rather than to the component first named.

PHENOMENOLOGY-NEUTRAL PROGRAMME

Separate functional organization from phenomenal interpretation

Use when loaded terms such as awareness, feeling, self, effort, memory, preference, or introspection threaten to carry hidden phenomenological or anthropomorphic commitments. Decompose, perturb, and preserve the phenomenal residual separately.

PARTICIPANT EVIDENCE

Ask the bearer when the target is partly first-person

Use when a dispute concerns a candidate's own preference, endorsement, objection, or good. Route the report through RCF's First-Person Participation operator: calibrate stability and reason-responsiveness, test manipulation and tradeoffs, and do not transport the result automatically into consciousness, welfare, or standing.

COMPUTATIONAL OBSERVER

Persistent high-information observation instrument

Use to capture anomalies, repeated dissociations, unexpected transfers, and other potentially important observations before they are mature enough for theory. The ledger records provenance and revision; it does not create evidential authority.

CONSTRAINT-CONDITIONED AGENCY

Reachable-state control without causal sovereignty

Use when agency, choice, free will, sourcehood, determinism, or responsibility are in dispute. Separate exact replay, physical branching, reachable alternatives, reasons-

responsiveness, local control, causal sovereignty, and normative responsibility before comparing theories.

EXTRACTION RULE

Separate only when separation earns its cost

A module deserves its own page when it has distinct triggers, variables, procedures, failure modes, tests, and reuse value that improve routing or performance. If a shorter parent-framework rule recovers the gain, keep it absorbed or re-absorb it.

Architecture rule: small kernel + selectively activated modules. Do not create a flat collection of equal-status frameworks merely because several useful operators have acquired names.

CURRENT STATUS

An active protocol that must earn its independence

The Bridge currently has a strong conceptual motivation and substantial overlap with existing RCF operators, Sweet Rationalism's pluralist ethos, and the scale-relative ontology's bridge discipline. It therefore does not yet warrant presentation as an independently validated fourth foundational framework.

Its immediate role is narrower and more useful: make cross-framework entry, translation, loss accounting, and tribunal negotiation explicit enough that people can use the existing architecture without first adopting its vocabulary or ontology.

The September 4 modularity pass also gives the Bridge an explicit routing role: cross-framework translation stays here, while observer-transformation identifiability, system-boundary attribution, phenomenology-neutral self-modeling, and persistent observation are incubated as specialized RCF modules or instruments. This keeps interoperability from becoming a universal container for every epistemic problem.

RETAIN Operators that measurably improve reconstruction, discrimination, or correction.

REVISE Operators that help but require narrower scope or better implementation.

DEMOTE Claims of novelty already recovered by established pluralist or interdisciplinary methods.

SUSPEND Claims whose added value remains plausible but untested.

COMPRESS Machinery whose gain can be recovered by a shorter RCF checklist.

PROMOTE Dedicated interoperability machinery that beats ordinary RCF and strong existing alternatives under matched evaluation.

DROP Components that increase ceremony without improving decisions, evidence transport, or error localization.

What would justify promotion to an independent framework?

Promotion would require evidence that framework interoperability has distinctive problems and operators not adequately captured by RCF alone. Candidate additions include many-to-many construct mapping, formal translation-loss metrics, tribunal-conflict resolution, framework-relative proof-duty maps, power-sensitive intake rules, and validated procedures for preserving untranslatable residuals.

If those additions generate novel discriminators, reduce measurable misrepresentation, improve cross-domain transfer, or enable cooperation where simpler methods fail, the

programme should be promoted. If not, it should remain what it currently is: a useful application layer.

PLAIN-ENGLISH FORMULATION

You do not have to become us before we can compare what we think

Bring the strongest version of your framework. Tell us what you are trying to explain or preserve. We will identify what your view and its strongest rivals already share, what each one adds, what gets lost when their vocabularies are translated, and what kind of evidence could actually bear on the remaining differences. If the evidence distinguishes them, revise. If it does not, keep the shared result and leave the rest open.

That means a physicalist does not have to become a process philosopher before the comparison starts. A process philosopher does not have to accept physicalism's definitions. A phenomenologist does not have to pretend lived structure is identical to neural measurement. A neuroscientist does not have to treat first-person certainty as a mechanism. A theologian does not have to abandon theological meaning in order to expose historical or causal claims to evidence. A skeptic does not have to accept the theological interpretation merely to take the experience seriously.

The protocol asks every side for the same thing: preserve what works, identify what you add, show what difference it makes, and remain capable of changing if the world pushes back.

> **Frameworks do not need one final language to share a reality check.**
